# Journal of the Society of Chemical Industry.

## INDEX OF VOL. XVI.—1897.

### INDEX OF AUTHORS' NAMES.

N.B.—In this Index (P) indicates that the matter referred to is an abstract of a Patent.  
The titles of new books are given in quotation marks.

#### LIST OF ABBREVIATIONS.

App. ....	Apparatus	Extract. ....	Extraction,ing	Prep. ....	Preparation
Applic. ....	Application,able	Ferment. ....	Fermentation,ing	Prev. ....	Prevention,ing
Artif. ....	Artificial	Formn. ....	Formation	Prod. ....	Production,ing
Atmos. ....	Atmospheric,sphere	Gen. ....	Generation,ing	Prot. ....	Protection,ing
Aurif. ....	Auriferous	Impt. ....	Improvement,s	Purif. ....	Purification,ing
Charac. ....	Character,istics	Infl. ....	Influence	Qual. ....	Quality,tative
Chem. ....	Chemical,s-istry	Manuf. ....	Manufacture,ing	Quant. ....	Quantity,tative
Co. ....	Company	Mat. ....	Matter,s	Rectif. ....	Rectification,ing
Col. ....	Colour,s-ation,ing	Mind. ....	Mineral,s	Separ. ....	Separation,ing
Comp. ....	Composition,pound,s	Modif. ....	Modification,ing	Soc. ....	Society, Societe
Concent. ....	Concentration,ing	Nat. ....	Natural	Sp. Gr. ....	Specific Gravity
Decomp. ....	Decompose-ition, ing	Org. ....	Organic,ism,s	Temp. ....	Temperature,s
Detec. ....	Detection,ing	Photo. ....	Photography,graph,s	Util. ....	Utilisation,ing
Determ. ....	Determine-ation,ing	Physiol. ....	Physiology,ical	Veget. ....	Vegetable,s-ition
Distill. ....	Distillate,tion,ing	Ppn. ....	Precipitation	Volum. ....	Volumetric
Estim. ....	Estimate,tion,ing			Vorm. ....	Normals
Evap. ....	Evaporate,tion,ing				
Exam. ....	Examine-ation,ing				
Expts. ....	Experiments				

#### A

	PAGE		PAGE
Abezz, R. Cathode Rays, Modif. of Salts by the Action of,....	919	Aichino, Sr. Sulphur, Extraction of, in Sicily .....	439
Abel, L. " Die Chemisch-Trockene Reinigung von Kleidungs- stücken," &c. ....	1052	Aignan, A. Oil of Turpentine, Detection of Rosin Oil in.....	764
Abell, W. P. Drying Apparatus, Centrifugal (P).....	56	Aird, H. W., and Feleh, C. E. Paint for Ships' Bottoms (P)...	685
Acetylen-Gaslicht Gesellschaft, Basel. Acetylene Gas, Appa- ratus for Generating (P) .....	527	Aismann, S. Oils, Mineral, Solubility of, in Absolute Alcohol	791
Actien Gesellschaft für Anilin Fabrikation. Colouring Matters, Manufacture of Black Mordant-dyeing (P) .....	735	Aitken, A. P. Turnips, Discussion on Composition and Man- nuring of .....	218
Colouring Matters, Manuf. of Direct-dyeing Azo (P) .....	40	Albrecht, F. Glass, Porcelain, &c., Production of Pictures, &c. on (P).....	799
Colouring Matters, Manufacture of Direct-dyeing, and Materials therefor (P) .....	233	Oven for Burning Designs on Glass and Earthenware (P)	339
Col. Matters of the Rosinduline Series, Manuf. of (P) .....	435	Alexander, F. W. Disinfection of Houses.....	1033
Adams, Cuprous Oxide Estimation, Discussion on.....	983	Alexander, H. Sand and Cement, Apparatus for Measuring and Mixing (P).....	1065
Sulphur Recovery, Discussion on.....	981	Alexandre, H. E. Acetylene, Apparatus for Manuf. of (P) ....	605
Addicks, W. R. Gas, Manufacture of Carburetted Water- (P)	729	Allan, F. H. T. See Simpson .....	619
Adeney, W. E., and Parry, W. K. Precipitants for Sewage, &c., Manufacture of, from Fine Dusts (P) .....	349	Allen, A. H. Electro-plating and Gilding Solutions, Assay of , And Cox, F. H. Cheese, Presence of Heavy Metals in.....	828
Adiasiewietzsch, A. W. Wood, Treatment of, with Petroleum Antiseptics .....	45	And Searle, A. B. Protein and Gelatinoid Substances, Determination of.....	1047
Aller, G. W. Hides and Skins, Method and Compound for Tawing (P).....	342	Alliott, J. B. See Halpin .....	602
Adler, M. Chalk, Dimorphism of Precipitated.....	767	Allison, J. W. Lamps, Hydrocarbon Incandescent (P) ..	790, 901
Adorján, D. Steam, Method and Apparatus for Producing Superheated (P) .....	428	Allport, H. A. See Crossley .....	546
Adrian, L. Guaiacol and Cresotes, Rapid Analysis of.....	266	Alsborg, M. Lake, Discussion on the Definition of a.....	416
Adrian, M. Guaiacol, Determination of, by Demethylation ...	367	Altmann, F. Flame, Apparatus for Generating Mixture for Production of Blue (P).....	902
Agate, W. See Noad.....	617	Fuel, Method and Apparatus for Burning Liquid (P) .....	654
Aglot. Hematein in Logwood Extracts, Estimation of .....	938	Altmann, P. Water, Rendering Drinking, free from Germs (P) .....	552
Tea, Analysis of .....	393	Altschul, M. Acetylene, Danzers of .....	319
Aguiar, A. d', and Silva, W. da. Wines, Distinguishing Coal- Tar Colours from Caramel in .....	563	Aluminium Industrie Aktien Gesellschaft, Electrolytic Ap- paratus (P) .....	746
Wines, Testing White, for Coal-Tar Colours, and Difference between those Colours and Caramel .....	361	Amend, O. P. Chrome Mordant on Animal Fibre, A New, .....	895, 897
Abrens, F. Sparteine Derivatives.....	256	Amege, C. Liquids and their Bottles, Protection of, during Sterilisation (P) .....	819
Abrens, F. B. Coal-Tar Bases .....	131	Amigo, F. See Colberg .....	799
		Amos and Co. Fabrics made of Fibre, Paper, &c., Waterproof- ing (P) .....	696

	PAGE		PAGE
Ansel, H. Driers, Solid or Liquid .....	685	Balden, I. N. V. Acetylene Gas, Method and Apparatus for Production of (P) .....	1007
Lansed Oil, Investigation of .....	820	Bach, A. Albumin, Action of Formaldehyde on .....	259
Varnish, Unboiled Lansed .....	924	Bachelier, C. L. Plants, Removal of Fibre from Textile (P) ..	1013
Anthony, C., and Zink, J. Fats, The Chemistry of Animal .....	247	Bachhaus, A. Milk, Rendering, Suitable for Food for Infants (P) ..	694
Anderslik, K. "Osmose Water," obtained by Evaporation .....	251	Backhaus, R., and Schach, P. Butter and Cheese, Manufacture of (P) .....	437
Anderson, J. K. Mineral Waters, Artificial (P) .....	628	Badische Anilin und Soda Fabrik. Colouring Matter from Dinitronaphthalene, Manufacture of (P) .....	436, 532
Anderson, J. W. "The Inspector's Handbook" .....	705	Dyes, Production of Yellow (P) .....	675
Andersson, W. C. Ammonium Sulphate Determination, Discussion on .....	594	Nitro Derivatives, Manuf. of New Prod. from Aromatic (P) ..	608
Andraud, A. Aluminium Phosphate from Grand Comptable, Manual Experiments with .....	687	Oils, Refining Crude, and Apparatus therefor (P) .....	38
Andre, G. See Berthelot .....	65	Phthalic and Sulpho-Phthalic Acids (P) .....	676
Andre, G. G., and Curtis, C. H. Explosives, Manufacture of Ammonium Nitrate (P) .....	560	Badische Anilin und Soda Industrie. Petroleum, Purif. of (P) ..	904
Andreassch, F. Tan Ligners, Fermentation Phenomena in .....	248, 349, 620, 747, 925, 1025	Banziger, E. See Gnehm .....	234
Androsch, E. Gold, Electro-Deposition and Recovery of .....	96	Bailey, Silks, Discussion on Adulteration of .....	405
Metals, Apparatus for Electrical Deposition of Precious (P) ..	150	Bailey, E. H. S., and Palmer, C. M. Cider, Salicylic Acid and Calcium Sulphate as Preservatives of .....	817
Ozone, its Commercial Production and Applications .....	80	Bailey, E. M. Ammonium Sulphate Determ., Discussion on ..	994
Androsch, G. Ozone Production and Application, Discussion on ..	95	Bailey, H. Oil in Greases with Lime Base, Determination of Unsaponifiable .....	1047
Andrews, J. Metals, Unting or Welding (P) .....	806	Bailey, R. D., and Ford, L. P. Mash-Tuns and Conversion Vessels (P) .....	349
Angel, H. R. Soda, Manufacture of Caustic, and Carbonate of, See (P) .....	43	Bailliere, J. B., et fils. "Les Nouveautés Chimiques pour 1897" ..	267
Angell, A., and Canby, F. Liquids, Materials for Filtration and Purification of (P) .....	629	Baird, W. H. See Stone .....	452
Sewage and Water, Preparations for Precipitants in Treatment of (P) .....	629	Baker, H. Efficiency of an Electrolytic Cell, Discussion on ..	105
Anstacher, L. Laki, Discussion on the Definition of a .....	116	Baker, J. L. See Ling .....	154
Anschutz, R. Tartrazine, Constitution of .....	324	Baker, T. J. Silver in Silver-plating Solutions, Estimation of ..	828
Anstaze, R. Starching Preparation, and Manuf. thereof (P) ..	928	Balbach, E. jun. Electrolytic Apparatus (P) .....	1022
Antisch, A. C. See Kotel .....	366, 471	Baldensberger, T. Turley Red, Dyeing of .....	237
Appert, L. Aluminium, Employment of, in Glass-making .....	43	Balland, Aluminium Utensils, Analysis of .....	699
Arachequesne, G. Alcohol, Denaturing .....	156	Bread, Note on a New Army .....	60
Beetroot Juice, Difficulties in Fermentation of .....	155	Ballantyne, H. Lamp, Discussion on a Slow-Combustion Arc ..	387
Dextrose in the Beetroot, Saccharogenic .....	342	Ballard, Guaiacol Phosphite and Phosphatol, Preparation of ..	632
Wood Spirit, Ethylic Alcohol in Raw .....	666	Ballard, E. G. Zinc, Volumetric Estimation of .....	399
Archbutt, L. Oils, Hehner's Bromine Thermal Test for .....	369, 311	See McGhie .....	1020
Sulphur Recovery, Discussion on .....	981	Ballo, M. Lard, Detection of Beef Fat in .....	764
Cuprous Oxide Estimation, Discussion on .....	983	Balthasar, O. Porcelain Flowers, Manufacture of .....	44
Sewage Filtration, Discussion on .....	28	Bamber, H. K. Cement, Adulteration of Portland, Discussion on ..	859
Archer, C. Lactic Acid as an Assistant in Mordanting Wool ..	140	Bamber, H. K. G. Cement, Discussion on Adulteration of .....	863
Argall, P. Cyanide Mill Solutions .....	917	Bamberger, E., and Einhorn, A. Fusel Oil, Bases contained in ..	253
Cyanide Process, Limitation of the .....	917	Bamberger, M., and Landsiedl, A. Resins, Exudation of .....	1024
Arledter, F. Soap, Manufacture of Resinous (P) .....	1023	Bandsept, A. Burners, Manufacture of Incandescent (P) .....	1007
Armstrong, H. E. Sulman-Tied Gold Process, Discussion on ..	969	Banville, L. de, and others. Leather Substitute, Manuf. of (P) ..	926
And Wynne, W. P. Chloronaphthalenesulphonic Acids, Conversion of, into Dichloronaphthalenesulphonic Acids .....	672	Barba. See Kayser .....	451
And Wynne, W. P. Dichloronaphthalene. Conversion of 1:1 into 1:2, by Hydrogen Chloride .....	673	Barbet, E. Alcohols, Analysis of .....	1048
And Wynne, W. P. Dichloronaphthalenesulphonic Acid, Products of Hydrolysis of 1:1 .....	673	Dextase in the Beetroot, a Saccharogenic .....	252
Armstrong, J. Metals, Extraction of, from Sulphides, Ores, or Mattes (P) .....	1020	Barbier, P., and Leser, G. Licarhodol, Dextro-Rotatory .....	697
Armstrong, J. T. Lamp, Incandescence Petroleum (P) .....	666	And Leser, J. Menthol, Formation of a .....	697
Armstrong, R. See Harzevics .....	798	Barclay, W. Manure, Production of Blood and Slag (P) .....	54
Arndt and Troest. Paper, Photographic .....	560	Bardach, B. Milk, Cause of Coagulation of Heated .....	628
Arnold, E. See Kipling .....	907	Barze, R. $\alpha$ -Anhydrosulphamine-benzoic Acid, Separation of, from $p$ -Sulphamine-benzoic Acid (P) .....	750
Arnold, J. O., and Knowles, F. K. Crucibles, Permeability of Steel-melting .....	540	Bavillot, E. Alcohol, Denaturing of .....	626
Arter, A. Gas, Treatment of (P) .....	605	Organic Products, Distillation of .....	693
Arth, G. Nitrogen in Purified Coal-Gas, Determin. of Free .....	170	Barker, A. H. Acetylene Gas Generators (P) .....	721
"Rechen de Procédés de Dosage" .....	267	Barnes, Zinc Dust, Discussion on Valuation of .....	15
Asboth, A. van. Butter and Margarine, Discrimination between .....	640	Barnes, F. C., and Campbell, F. Aluminium or Alloys, Soldering (P) .....	335
Aschan, O. Zinc Dust as an Oxidising Agent .....	475	Barnes, J. Titanium Oxide, Production of Fast Colours on Animal Fibre by (P) .....	238
Aschermann, Chromium, Electro-Metallurgical Process for Obtaining (P) .....	922	Baron, A. F. M. V. Alloy of Copper and Iron, Manuf. of (P) ..	617
Aschermann, H. Alloys and Pure Metals, Extraction of, by Electric Heat. (P) .....	116	Baron, C. Degras, Artificial Manufacture of .....	922
Ash, T. M., and Weldon, H. N. Electro-Plating, Preparing Non-Metallic Substances for (P) .....	216	Wool-Fat, Purification of .....	447
Ashcroft, E. A. Ores containing Zinc, Treatment of (P) .....	684	Barral, E. Disulphuric Acid, Colour Reaction for .....	762
Ores containing Zinc, Treatment of Solutions of (P) .....	685	Barret, C. T. Storage Battery (P) .....	545
Ores, Treatment of Metalliferous (P) .....	50	Barrière, P. Mantles, Incandescent, from "Lucium" (P) .....	36
Ashworth, A. Coal Matters, Manuf. of Grey and Black (P) ..	907	Basch, A., and Gruepel, H. Combustibles, Carbonising, Charring, or Coking (P) .....	902
Asselt, M. E. Celluloid, Manuf. of Unmouldable (P) .....	151	Basic Chemical Works, Bindscheller. Dyestuffs of the Phthalic Series, Production of (P) .....	676, 677
Atkinson, J. E., and Labouchere, J. M. Acetylene Apparatus for Automatic Manufacture of (P) .....	604	Basilius, H. W. J. Van Otterbeek. Cloths for Oil and Filter-Presses (P) .....	428
Atkinson, L. B., and Tcharne, F. G. Electric Batteries. (P) ..	617	Bastin, E. S., and Trimble, H. "Some North American Conifers" .....	942
Attfield, J. Barium Peroxide, Discussion on Danger of Fire from .....	193	Bateman, T. H. Soap, Manufacture of Liquid (P) .....	619
Aubry, L. Malt, Storage of Kilned .....	625	Bates, F. G. Gas, Manufacture of, and Apparatus therefor (P) ..	431
Auehmachie, P. Waters, Manufacture of Aromatic (P) .....	64	Bathandler and Malosse. Retamine: a New Alkaloid .....	932
Auwers, K., and Rohrer, H. Oxyazo Compounds and Triphenylazo Derivatives .....	667	Bauligny, H. Antimony, Estimation of, as Tetraoxide .....	470
Aweng, E. Tannin, Estimation of .....	394	Antimony Tetraoxide, Decomposition of, at High Temp. ...	475
Axheim, L. Soap made with Carbon Tetrachloride .....	59	And Rivas, P. Chlorine and Bromine, Separ. and Estim. of ..	635

	PAGE		PAGE
Baudouin, H., and Schribaux, E. Liquids, Method and Apparatus for Concentrating (P).....	719	Bertrand, G. Laccase, Influence of Manganese on Oxidising Power of.....	626
Baudrier, L. See Nieloux.....	473, 1047	Laccase, Intervention of Manganese in Oxidising Actions of.....	626
Baummann, S. See Claus.....	756	Besso, M. See Renold.....	251
Baumgartner, A. Plates for Obtaining Coloured Photographs (P).....	64	Besson, A. Phosphorus, New Oxide of.....	612
Bauwmeesters, E. F. J. C. Gas, Method and Apparatus for Carburetting (P).....	963	Bettel, W. Cyanide Process, Prof. Christy on the.....	739
Bayley, J. C. Acetylene, App. for Generating and Storing (P).....	320	Bevan, E. J. Barium Peroxide, Discussion on Danger of Fire from.....	436
Bean, H. R., and Ringwood H. Acetylene and other Gases, Generator, Condenser, and Holder for (P).....	527	London Water Supply, Discussion on.....	185
Beanes, E. Ozone Generators, Note on.....	395	See Cross.....	252, 691
Beaudet, L. Beetroot Juice and Liquor, Filtration of.....	622, 622	Beveridge, A. See Spence.....	721
Beaven, E. S. Malt, Discussion on Relation of Colour to Value in.....	191	Beveridge, S. M. See Spence.....	721
Bécherel, C. P. J. B. Acetylene Gas, Apparatus for Manufacture of (P).....	790, 791	Beveridge, W. G. See Spence.....	721
Becker, E. Lamps, Incandescent Spirit (P).....	604	Bhaduri, J. Chlorate, Conversion of Hypochlorite into.....	440
Beckmann, E. Camphor Series, Researches in the.....	255, 256	Bilobrzek, M. Butyltoluene, Tertiary p., and its Nitro Derivatives.....	823
Bedford, J. E. and C. S. Varnish, Manufacture of Copal (P).....	1024	Bichel, C. E. Nitroglycerin Explosives, Manufacture of (P).....	584
Bedson, P. P. Coke, Discussion on Sampling and Analysis of.....	308	Bickford, J. S. V. Furnaces, Crucible (P).....	1020
Beer, W. See Maxwell, F. W.....	145	Biedermann, R. "Chemiker-Kalendar".....	942
Besson, J. L. Sugar-Cane Juice, Clarification of.....	343	Biehringer, J. Pyronine Dyestuffs, Constitution of.....	134
Béhal, A., and François, M. Chloroform, Analysis of.....	566	Bielefeldt, M. Explosives, Manufacture of (P).....	825
Behrend, Barley, Influence of Drying, on Germination.....	549	Billaudet, L. L. Phosphorus, Electrical Manufacture of (P).....	745
Behrens, J. Hops, Sulphuring of.....	154	Billing, F., and Letalle, A. Leather, Substitute for (P).....	817
Beilby, Brewing Materials, Discussion on Analysis of.....	314	Bilteyst, A. Chocolate, Detection of Earth Nuts in.....	567
Beilby, G. Cyanide Solutions, Discussion on Residual.....	121	Fat in Oil-Cakes, Estimation of, by Carbon Tetrachloride.....	565
Proceedings of Annual Meeting.....	594	Birch, W. Sewage and Impure Liquids, App. for Filtering (P).....	459
Speech at Annual Dinner.....	598	Bird, F. C. J. Petroleum, Medicinal.....	727
Beilby, G. T. Address to Scottish Section.....	874	Bitto, Bela von. Aldehydes and Ketones, Colour Reactions of.....	700
Ammonium Sulphate Determination, Discussion on.....	994	Blachstein, A. Chrysoidine, Behaviour of, towards Cholera Bacilli.....	168
Retort, Discussion on the Pumpherton.....	992, 993	Blackmore, H. S. Aluminium: Binary Compounds and their Reduction.....	219
Shale Retorts, Discussion on.....	988	Sodium, Synopsis of the Metallurgy of.....	219, 222, 223
Beindorff, F. Colours for Water-Colour Painting (P).....	546	Blackmore, W. Gold, Silver, or Platinum, Treating Ores, Ac. containing (P).....	48
Belfort, L. A. M. D. de. Preserving Apparatus (P).....	1005	Blaile, A. Musk, Manufacture of Artificial (P).....	559
Bell, G. and G. W. Electrolytic Apparatus (P).....	618	Blair, A. A. Iron, Determination of Sulphur in Pig.....	469
Bell, H. J., and Niagara Falls Acetylene Gas Machine Co. Acetylene Gas, Apparatus for Prod. and Storage of (P).....	1008	Blake, M. See Jack, J.....	247
Bell, J. Carter. Sewage, Disc. on Dealing with Manchester.....	18	Blakeley, J. F. Acetylene and other Gases, Apparatus for Generating (P).....	230
Silk Adulteration.....	303	Blank, R. Dyestuffs of Indigo Series, Compounds of, with Indoxyl Acids (P).....	731
See Wardle.....	297	Bleier, O. Gas-Analysis Apparatus.....	466, 634
Belugou, G. Strontium Chromate, Action of, on Mercuric Chloride.....	560	Nitrogen, Combustion of.....	639
See Imbert.....	569	Block, J. See Ganelin.....	617
Bennelmann, L. Gas Producers, Process for Burning Poor Coal in (P).....	130	Blomen, J. E. See Kreuz.....	933
Bendixen, N. Yeast and Bacteria, Propagating App. for (P).....	751	Blount, Bertram. Cement, Adulteration of Portland.....	853, 862
Benedikt, R. "Analyse der Fette und Wacharten".....	570	Explosives, Discussion on Stability of Nitro Compound.....	261
Bencke, G. Explosives, Manuf. of Ammonium Nitrate (P).....	560	London Water Supply, Discussion on.....	184
Bencke, G. and H. Colloid Paper for Positives.....	550	Ozone Production and Application, Discussion on.....	95
Benkert, A. L., and Smith, E. F. Bismuth and Lead, Separ. of.....	164	Pyrometer, Discussion on a Recording.....	8
Bennett, J. E., and Beresford, H. Fluids, Filtering (P).....	719	Bloxam, A. G. Cement, Discussion on Adulteration of.....	861
And Beresford, H. Tanks for Filtering and Precipitating Sewage (P).....	753	Blumenfeld, S., and Friedlander, P. Quinones, Reaction for Aromatic.....	764
Bennett, J. T. Wines and Spirits, Apparatus for Purifying (P).....	349	Blumenthal, F. See Nietzki.....	232
Bennett, S. Fabrics, Rendering, Impervious to Climate and Moisture (P).....	620	Blumer, E. R. L., jun. Dressing for Woven Fabrics (P).....	237
Benneville, J. S. de. Iron, Passive.....	941	Blunck, J. Hides, Rapid Process of Tanning.....	249
Silicic and Tungstic Acids, Separation of.....	686	Blunden, O. G. Manure, Artificial, and Manuf. thereof (P).....	451
Bentley, H. Yarn, Apparatus for Scouring and Dyeing (P).....	912	Bocandé, J. E. O. See Gillett, S. D.....	230
Bentz, E., and Farrell, F. J. Dyeing, Theory of.....	495	Bocchi. Filicic Acid in Extract of Male Fern, Determ. of.....	568
Bercham, P. van. See Bonna.....	684	Bocquillon-Limousin, A. Iodoformin, and Iodethylformin, Preparation of.....	757
See Le Royer.....	836	Bodlander, G. Cyanide Process, Chemistry of the.....	45
Berens, L. H. See Singer.....	475	Boehm, R. Arrow Poison from the Larva of a Beetle.....	570
Beresford, H. See Bennett.....	719, 753	Boehringer, C. F., and Solne. Cinnamic Aldehyde, Manufacture of (P).....	463
Bergé, A. Starch, Transformation of, by Sulphur Dioxide.....	548	Isoeugenol and its Derivatives, Preparation of (P).....	755
Berland, E., and Girard, J. Paper Pulp from the Broom Plant, Manufacture of (P).....	670	Theobromine, Manufacture of (P).....	754
Bernhardt, F. A. Fibres, Mercerising Vegetable (P).....	677	Trichloropurine, Production of (P).....	754
Bernstein, A. Milk, Treatment of (P).....	280	Boehringer Sohn, C. H. Colouring Matters, Preparing Solutions of (P).....	674
Bernstein, M. Burners for Incandescent Lighting (P).....	903	Fibres, Mordanting Wool and other Animal (P).....	674
Marble, Production of Artificial (P).....	145	Mordanting Agent and Process (P).....	757
And Ehrenbacher, M. Burners, Incandescent Oil Vapour (P).....	1007	Boese, W. A. Plates for Accumulators, Manufacture of (P).....	618
Berntrop, J. C. Lead in Water, Detecting and Estimating.....	66	Boettlinger, C. Glycerin in Wine, Determination of.....	1048
Berry, J. Waterproofs, Pritzing, and Apparatus therefor (P).....	42	Hubl's Iodine Solution, Behaviour of Tannic Acids, &c. towards.....	649
Berte, E. See Soldini.....	266	Böttinger, H. T. Speech at Annual Dinner.....	598
Berthelot. Mercury, Direct Action of Sulphuric Acid on.....	1051	Rohne, C. C. E. Slag from Tin Ore, Treatment of (P).....	914
Sulphuric Acid, Action of Hydrogen on.....	1051	Boidin, A., and Rolants, E. Yeast, Utilisation of Chinese, in European Industries.....	454
And André, G. Pyrophosphoric Acid, Estimation of.....	65	Boisly, G. See Hlammemann, A.....	323
And Vieille. Acetylene, Solutions of, and their Explosive Properties.....	787, 788	Boisne, H. and L. See Germain.....	428
Bertolus, C. See Chesnay.....	721, 903	Boisseher, H. Coffee, Manufacture of (P).....	349
Bertrand, E. Open-Hearth Process of Bertrand and Thiel.....	542		

	PAGE		PAGE
B. Korny, T. Fermentation, Regarding Influence of Various Reagents on.....	58	Brock, J. See Courroy.....	412
N. Kraschewski, Toxic Power of.....	61	See Buff.....	537
Phosphorus, Solubility of in Water.....	61	See Glover.....	601
Phosphorus, Toxic Action of Aqueous Solutions of.....	61	See Wyde.....	448
Starch Formation.....	174	And Hurter, F. Sulphur, Recovering, from HS (P).....	539
Yeasts, Carbohydrate Feeding of Baking.....	345	Brodieck, C. Fabrics from Paper-Pulp, Manufacture of (P).....	327
B. Las, T. Wall Papers, Cause of Arsenical Poisoning by.....	820	Brodrick, J. H. Drinks, Compounds for Non-intoxicating (P).....	627
Balder, H. Glycerin, Preparation of Liquid Casein of.....	1026	Brook, F. V. C. Vaporiser for Incandescent Lighting (P).....	1007
Balog, F. Petroleum, Refining, with Fuming Sulphuric Acid.....	1009	Bromberg, O. See Fischer, E.....	256
Turpentine and Rosin, Treatment of Crude.....	812	Bromly, A. H. Gold Mining in Burma.....	443
Baumel, L., and Sauter, Bisson, Bepres, and Co. Accumulators, Negative Electrode for (P).....	715	Bronnert, E., and Schluenger, T. Teirmitro Cellulose, Manufacture of (P).....	355
Baum, V. Textiles, Manufacture of (P).....	1013	Brookfield, S. M. See Robinson.....	443
Bonardi, J. F. G. de. Garbage, Method and Furnace for Incinerating (P).....	1034	Brown, A. G. Rods or Tubes from Aluminium or Alloys (P).....	445

Zerener, M. B. Metals, Precipitation of, from Cyanide Solutions (P) .....	544	Zsigmondy, R. Glass, Colouring, with Silver .....	1015
Zervas, J. Puzzolana and its Practical Use .....	612	Glass containing Silver, Surface Lustre in .....	1015
Zimmermann, A. Calcium Soap, Formation of, during Boiling of Soda Cellulose .....	630	Zulkowski, P. Glass Coloured by Copper .....	441
Zimmermann, J. Acetylene and other Gases, Method and Apparatus for Forming and Burning (P) .....	320	Zwick, K. G. Bixin, Separation of .....	1041
		Zwilling, N. See Pollak .....	442

## INDEX OF SUBJECTS.

N.B.—In this Index, (P) indicates that the matter referred to is an abstract of a patent; (T.R.) indicates that the matter referred to is in the Trade Report.

	PAGE		PAGE
A		Acetylene— <i>cont.</i>	
Absorbing Apparatus for Gases. (Arndt).....	935	(P) Wetter. From Meyer.....	1007
Acarina, Presence of, in Wine. (Mathieu).....	818	Gas, Apparatus for Generating and Storing. (P) Bayley..	320
Acaroid Resin, Yellow and Red. (Hildebrand).....	340	(P) Bowers.....	721
Acetaminol. <i>See under</i> Batteries, Secondary.		(P) Chesnay and Pillion.....	790, 790
Acetamide or Acetolides, Production of. (P) Fell. From		(P) de Roussy de Sales.....	605
Matheson and Co.....	559	(P) Gibbon.....	665
Separation of, by Micro-chemical Tests. (Schöpp).....	361	(P) Kay.....	721
Acetates, Denaturing of. (T.R.).....	774	(P) Thompson. From Comucci.....	721
Production of. (P) Schmidt.....	611	(P) Thorn and Hiddle.....	601
Acetic Acid as an Assistant in Dyeing. (Wainwright).....	437	Gas, Apparatus for Generating, Storing, and Delivering.	
Acid Bacteria, Physiology and Morphology of the. (Seiferl.)	1031	(P) Chesnay and Pillion.....	905
Acid Fermentation. (Andrueschi).....	52	Gas, App. for Generation and Distribution of. (P) Tobler	320
Acid in Italian, Greek, and Spanish Red Wines. (Ecken-		Gas, Apparatus for Manufacture of. (P) Alexandre.....	605
roth).....	58	(P) Atkinson and Labouchere.....	604
Acid, Production of, from Wood. (Klar).....	722	(P) Becherel.....	790, 790
Acid, Production of Pure. (Klar).....	667	(P) Cousin.....	605
Acid, Purification of Crude. (P) Schmidt.....	249	(P) Kesselring.....	790
Bacterium, A New. (Zedler).....	492	(P) Pym and Gore.....	250
Ether and Ethyl Alcohol, Volumetric Determination of		Gas, Apparatus for Obtaining. (P) Maxim.....	338
Mixtures of. (Kuriloff).....	473	Gas, Apparatus for Producing. (P) De Resener.....	903
Acetolides, Production of. (P) Fell. From Matheson and Co.		(P) De Resener and Luchaire.....	903
Acetonalkamms, Manuf. of Isomeric Unsymmetrical, and		(P) Lebrun and Cornaille.....	1008
Derivatives. (P) Chem. Fabrik vormals E. Schering.....	1038	(P) Richard-Lagerie.....	1007
Acetone, Condensation of. (Raikow).....	570	(P) Rieffel.....	1038
Estimation of. (Kebler).....	367	(P) Thompson. From Gerard.....	903
Halogen Derivatives, Preparation of. (P) Lederer.....	933	(P) Thompson. From Marc and Gerard.....	1008
Improvement of Squibb's Method for Estimating. (Kebler)		(P) Thorp and Marsh.....	903
Mesitylene from. (Meyer and Molz).....	38	(P) Trendel.....	721
Production of, from Wood. (Klar).....	722	Gas, App. for Producing and Burning. (P) Windmüller.....	1008
Production of Pure. (Klar).....	667	Gas, App. for Prod. and Storage of. (P) Bell and others ..	1008
Volumetric Determination of. (Squibb).....	168	(P) Carter.....	431, 1008
Acetosulphanilate Salts, Manufacture of Pure. (P) Hoffmann,		(P) Chesnay and others.....	903
La Roche, and Co.....	824	(P) Clausolles.....	430
Acetyl Derivatives of Aniline and Phenetidine, Preparation of.		(P) Kerr and Fry.....	665
(P) Lederer.....	258	(P) Morton-Brown and Maundrell.....	665
Derivatives of Phenetidine-sulphonic Acid Salts, Manufacture		(P) Trouvé.....	430
of. (P) Hoffmann, La Roche, and Co.....	758	Gas, App. for Prod. and Using. (P) Vaughan-Sherrin.....	903
Acetylene, Action of, on Cupric Salts. (Soderbaum).....	569	Gas, Apparatus for Producing, Storing, and Applying.	
App. for Generating and Storing. (P) Chesnay and others		(P) Holliday.....	527
Apparatus to Generating and Utilising. (P) Reitmeyer.		Gas, App. for Prod. and Application of. (P) Holliday.....	319
From Gerckel.....	320	Gas, App. for Production and Combustion of. (P) Tarr.....	231
Apparatus for Generation of. (P) Boulé. From Fuller.....	450	Gas, App. for Prod. and Consumption of. (P) Thompson.	
Apparatus for Manuf. of. (P) de Resener and Luchaire.....	790	From The Deutsche Acetylen-Gesellschaft.....	665
Apparatus for Producing. (P) Juneno.....	1008	Gas, Apparatus for Prod. and Treatment of. (P) Dargue.....	1008
Apparatus for Production of. (P) Gastmeier.....	630	Gas, Apparatus for Production of. (P) Bablon.....	1007
Asa Quantitative Reagent. (Soderbaum).....	562	(P) Fournier.....	902
Bunsen Burner for. (Munby).....	524	(P) Luis.....	230
Estimating. (Chavastelon).....	828	(P) Quatmann-Moens and Carreer-Dilger.....	665
Explosibility of Liquid. (Clowes).....	290	(P) Redfern. From La Comp. Continentale d'Eclairage	
Explosive Properties of Solutions of. (Berthelot and		par Acetylene.....	665
Vuille).....	787	(P) Voigt.....	665
Fire Office Regulations on. (T.R.).....	240	Gas, Bicycle Lamps for Burning. (P) Lake. From The	
For Lighting Purposes. (Buller).....	787	Wizard Manufacturing Co.....	1008
Form of Mixed Hydrates of. (De Foreaud and Thomas).....	832	Gas, Danger Limit of. (T.R.).....	885
Gas, Apparatus for Automatic Production of. (P) Hadidan		Gas, Facilitating Combustion of. (P) Coppeaux.....	526
Gas, Apparatus for Developing. (P) Thompson. From		Gas for Generation of Power, Application of. (Schrey).....	525
The Deutsche Acetylen-Gesellschaft.....	605	Gas Generator, Automatic. (P) Smith.....	790
Gas, Apparatus for Generating. (Blakeley).....	230	Gas Generator, Construction of. (P) Duffield.....	721
(P) Brewer. From The Gesellschaft für Acetylen-		Gas, Generator, Condenser, and Holder for. (P) Bean and	
Gashalt, Basel.....	527	Ringwood.....	527
(P) y Franco.....	605	Gas, Generator for. (P) Fernand des Essards.....	527
(P) Haviland and others.....	727	Gas Generator, Purifier, and Holder. (P) Smith.....	230
(P) Lake. From Ferenczy.....	528	Gas Generators. (P) Barker.....	721
(P) Lake. From Grenier and Grand.....	721	(P) Campbell.....	790
(P) Mackenzie.....	903	(P) Gedin.....	791
(P) Marks. From Bowers.....	791	(P) Jordan. From The Morley Acetylene Gas Co.....	527
(P) Mitchell.....	605	(P) Lake. From Hanotier and Hostelet.....	250
(P) Morency.....	605	(P) Spence and others.....	721
(P) Quille.....	320	Gas Generators and Gasometers. (P) Maudock and Jones	
(P) Schumacher.....	320	Gas Generators, Construction of. (P) Whalley and Hack-	
(P) Webb, Jun., and Kelly.....	527	ling.....	430
		Gas, Incandescent Lighting by. (P) Edwards. From	
		Therr.....	901
		Gas Lamps and Generators. (P) Dennis.....	527
		Gas, Manufacture of. (P) Peire and others.....	527
		Gas, Means for Regulating Production of. (P) Gossart	
		and Chevillier.....	1007
		Gas, Method and App. for Generating. (P) Fourchette ..	527

	PAGE		PAGE
Acetylene— <i>cont.</i>		Alcohol, Aldehyde in, Estimation of. (Paul)	265
Gas, Method and App. for Prod. (P) Trendelenburg	320	And Water, Distillation of Dilute Mixtures of. (Nieloux and Baudier)	473
Gas, Method and Apparatus for Producing and Burning. (P) Zimmerman	320	Apparatus for Purification of Crude. (P) Killmeyer	550
Gas, Method and Apparatus for Producing and Purifying. (P) Schmidt and Kaufman	230	As a Disinfecting Agent. (Epstein)	931
Gas, Method and Apparatus for Production and Treatment of. (P) Oving	721	Denaturing. (Arachequesne)	156
Gas, Method and Apparatus for Production of. (P) Thompson. From Chloride	665	Denaturing. (Barillet)	626
Gas, Plant and System for Production of. (P) Goodwin	320	Derived from Cellulose and Wood	58
Gas, Production of. (P) Day	527	Estimation of. (Richmond)	69
Gas, Production of. (P) Fitzgibbon	730	Estimation of, by the Vaporimeter. (Rothenbach)	642
Gas, Rendering Inactive in Contact with Certain Metals. (P) Isaacs	527	Ethyl and Glycerin, Determination of. (Nieloux)	566
Generation and Storage of. (P) Gaskell and Gibbs	721	Ethyl, Distill. of Highly Diluted. (Nieloux and Baudier)	1047
Generation and Storage of. (P) Gibbs	130	Ethyl, in Raw Wood Spirit. (Arachequesne)	667
In 1886, Report on	318	From Grain in the Manufacture of Coal-Tar Dyes. (Prochazka)	223
Its Dangers and their Prevention	319	In Canada. (T.R.)	73
Manufacture of. (P) Lewes	130	In Milk, Occurrence of. (Weller)	1033
Method and Apparatus for Manufacture of. (P) Pictet	37	Methyl, Determination of. (Nieloux)	941
Method and Apparatus for Purifying. (P) Pictet	37	Preparation of Ether free from. (Fritzsche)	631
Or other Rich Gas, Method of Burning. (P) Wigham	230	Alcohols, Analysis of. (Barlet)	1048
Poisonous Action of. (Mosso and Ottolenghi)	930	In Spirits, Estimation of the Higher. (Roques)	1048
Process and Apparatus for Generating and Liquefying. (P) Fraser	665	In Tunis. (T.R.)	708
Propagation of Decomp. of. (Berthelot and Vieille)	788	In Wool Fat, Action of Sulphuric Acid on. (Von Cohenhausen)	447
Purification of. (Lange and Cedercreutz)	1016	Unsaturated, Saponification of. (Henriques)	746
Regulations in Paris. (T.R.)	73	Alcoholic Liquids, Apparatus for Treating. (P) Johnson. From The Electric Rectifying Company	456
Remarks on Explosive Decomposition of Solutions of. (Berthelot and Vieille)	788	Preparations, American Drawback on. (T.R.)	708
Solution of, in Acetone. (Bothamley)	588	Aldehyde in Alcohol, Estimation of. (Paul)	265
Storing. (Claude and Hess)	524	In Ether, Determination of. (Francis)	701
Treating, prior to Combustion. (P) Thorp and Marsh	601	Method and Apparatus for Producing Vapours of Formic. (P) Trillat	754
Acid Filling. (Richard)	736	Aldehyde, Paraformic, as an Antiseptic. (Paul and Cowley)	754
Proof Electrical Non-conducting Articles, Composition for. (P) Morison	867	Production of Vapours of Formic. (P) Trillat	485, 821
Used in Nitro-Glycerin Manufacture, Denitrating. (P) Kynoch and Co., and Corking	825	Vapour, Distributing Formic. (P) La Societe Chimique des Usines du Rhone	751
Waste, from Metal Works, Report on. (Polbrooke)	801	Vapours, Formic, Production of. (P) Ellis. From La Societe des Usines du Rhone	1034
Acids, Alkalis, and Salts. (Class VII.)	42, 141, 238, 328, 439, 535, 610, 678, 737, 797, 912, 1015	Aldehydes and Ketones, Colour Reactions of. (von Bittro)	709
Consumption of Organic, by Yeast. (Schukow)	169	Apparatus for Producing Vapours of. (P) Fournier	695
Foreign Competition in, in Canada. (T.R.)	771	Development with. (Lumiere and Seyewetz)	259
In Mineral Oils, Estimation of Free. (Zaloziecki)	362	Manufacture of Aromatic. (P) Murray. From The Farbwerke vormals Meister, Lucius, and Brumme	558
In Wine, Estimation of Volatile. (Gayon)	766	Synthesis of Aromatic. (Gattermann and Koch)	832
Milling with	130	Alc, Pale, Manufacture of. (P) Fraser, and MacLay and Co.	1032
Mixing and Conveying, for Nitroglycerin Manufacture. (P) Kynoch and Co., and Corkings	934	See also under Beer.	
Vessels for Holding. (P) Fumak	227	Alc and Beers, Material for Brewing or Priming. (P) Valentin	456
Acridine Yellow, Oxidation of Potassium Percarbonate Lencoe Base to. (Lynn)	406	Algae, Fixation of Nitrogen by. (Bouillhae)	72
Address, Changes of. 2, 86, 182, 282, 384, 491, 584, 658, 718, 784, 852, 900		Algeria, Phosphate Concessions in. (T.R.)	770
Presidential. (Schunck)	586	Phosphates Deposits of. (T.R.)	810
To Liverpool Section. (Kohn)	863	Alizarin, Analytical Methods of Manufacturing. (Perkin)	563
To Manchester Section. (Davis)	868	Alkali-Cellulose, Manufacture of. (P) Cross	559
To Nottingham Section. (O'Sullivan)	977	Chlorides, Analysis of, by Means of the Telephone. (Erdmann)	636
To Scottish Section. (Beilby)	874	Estimation of Caustic. (Lunge)	262
Adhesive Compounds, Manuf. of. (P) Boulton, From Higgins	455, 625	Percarbonates, Manufacture of, by Electrolysis. (P) Constant and Von Hansen	537
Adzuki Bean, Protein of the White Podded. (Osborne and Campbell)	820	Sulphates, Artificial Stone capable of Resisting. (Hempel and Seziarski)	442
Aerating, Method of. (P) Hargreaves	1004	Works, Thirty-third Annual Report on. (Carpenter)	678
Africa, Classification of Sulphuric Acid in Portuguese East. (T.R.)	613	Alkalis. (Class VII.)	42, 141, 238, 328, 439, 535, 610, 678, 737, 797, 912, 1015
Air and Gases, Furnaces for Consuming and Deodorising. (P) Smith	695	Action of, on Citral. (Verley)	351
And Lime, Purification of Gas by. (Carpenter)	318	And Zinc, Electrolytic Production of. (P) Dieffenbach	335
Apparatus for Purifying. (P) Edwards	694	Artificial Stone capable of Resisting Fused. (Hempel and Seziarski)	442
Apparatus for Separation of Oxygen from. (P) Hampson	315	Obtaining Caustic, from Alkaline Aluminates. (P) Peniakoff	536
Carburetted, for Incandescence Gas Light, Method and Apparatus for Producing. (P) Kahns	1007	Preparation of Bromides and Iodides of. (Knobloch)	553
Carburettor, New System of. (P) Peugeot	37	Volumetric Estimation of. (Kuster)	163
Charging, with Combustible Matter. (P) Denayrouze	56	Alkaloid from Coffee, A New. (Forster and Riechmann)	631
Estimating Weight of Solid Matter in. (Cohen)	411	From Dioscorea Hirsuta. (Schuetter)	1037
Gases and Vapours, Apparatus for Electrical Treatment of. (P) Bonner, Le Royer, and Van Berchem	684	Retamine, A New. (Battandier and Malesse)	932
In Gasworks Houses, Contamination of. (Drehschmidt)	752	Alkaloids. (Class XX.)	42, 141, 238, 328, 439, 535, 610, 678, 737, 797, 912, 1015
In Mines, Electric Device for Controlling. (P) Colin	231	Action of Tannin and Gallic Acid on. (De Coninck)	639
Ozonised, Apparatus for Production of. (P) Verley	618	Action of Tannin on. (De Coninck)	479
To be Burned in Lamps, Means for Heating. (P) Niemeyer	37	And their Salts, Estimation of Water in. (Dott)	265
Albumin, Action of Formaldehyde on. (Bach)	259	Characterisation of. (Adam)	165
Bodies, Prod. of Formaldehyde Compounds of. (P) Classen	350	Determination of. (Farr and Wright)	366
Estimation of Commercial Egg-. (Carles)	767	Isolated from a Species of Jaborandi. (Petit and Polonovski)	461
Fixation of Pigments with. (Flintoff)	109	Limit of Sensibility of Marue's Reagent to. (Vervin)	567
Manufacture of, at Chikiang	327	Alloy, Manufacture of a Metallic. (P) Barnacott	616
Prep. of. (P) Comp. Parisienne de Couleurs d'Aniline	736	Manufacture of a New. (P) Ducac	682
Albumins, Putrefaction of. (Emmerling)	110	Manufacture of a New. (P) Sugg	682
Albuminoid Matter in Brewings on Wahl and Windisch Systems. (Henius and Thievent)	928	Of Copper and Iron, Manufacture of. (P) Baron	617
Structureless, with Bottom Fermentation Yeast. (Will)	1039	Of Tungsten-Iron. (Norton)	444
Albuminoids, Action of, in Producing Lasting "Heads" in Beer. (Windisch)	58	Alloys, Aluminium	244
In Substances Rich in Starch, Estimation of. (Tryller)	264	Analysis of Aluminium. (Jenn)	349
Of Cows' Milk. (Storch)	627	Assay of Nickel-Copper. (Riche)	937
Albuminous Compounds, Manufacture of New. (P) Murray. From The Farb. vorna, Meister, Lucius, and Brumme	558	Chromium, Manufacture of. (P) Street	616
Matter, Treatment of, for Use in Manufactures and Arts. (P) Sanford	816	Composition of New. (P) Van Wart, Popp, and Bradley	616
Substances, Preparation of. (P) Finkler	349	Constitution of Metallic. (Charpy)	615
		Containing Zinc, Freezing-Point Curves of. (Heggeck and Neville)	334
		Electrical Coating of Metals with. (P) Snyder	545
		Electro-Deposition of. (P) Webb and Thoms	447
		Electrolytic Preparation of. (Walter)	619
		Manufacture of. (P) Hadfield	919
		Manufacture of. (P) Street	682

PAGE

Antimony and Arsenic, Detection of. (Conradson).....	518
And Tin, Electrolytic Separation of. (Waller).....	1013
And Tin, Separation of. (Hallopeau).....	358
Arsenic, and Tin, Method of Separating. (Dancer).....	103
Arsenic, and Tin, Qualitative Separation of. (Rawson) ..	113
Estim. of, as Tetroxide. (Baubigny).....	170
Fluoride Salts. (Erhardt).....	41
Fluoride Salts. (Erlenmeyer).....	41
In Copper, Estimation of. (Holland).....	164
Lactate as Mordanting Agent for Vegetable Fibres. (P) Boehringer Sohn.....	737
Ores, Treatment of. (P) Claus.....	746
Separation of Arsenic from. (Piloty and Stock).....	754
Separation of, from Precious Metals. (Vavine).....	935
Tetroxide, Decomposition of. (Baubigny).....	475
Antipyretic, Cosaprine, A New. (Schwarz).....	631
Cosaprine, A New. (Von Vamossy and Fenyvessy).....	1038
Phesine, A New. (Von Vamossy and Fenyvessy).....	1038
Antipyretics, Manuf. of. (P) Hoffmann, La Roche, and Co. ..	758
Manufacture of Pure. (P) Hoffmann, La Roche, and Co. ..	824
Antipyrine, Combinations of, with Phenol, Constitution of. (Patein).....	462
Compound of, with Mercuric Chloride. (Hirsch).....	164
Compounds with Phenols. (Patein).....	353
Estimation of. (Kippenberger).....	266
Anti-Rheumatic Agent, Preparation of an. (P) Johnson. From The Vereinigte Chemiefabrik Zimmer and Co. ..	64
Antiseptic, Paraformic Aldehyde as an. (Paul and Cowley) ..	734
Antiseptics in Food Products. (Jeann).....	1032
Treatment of Wood with Petroleum. (Adasiewicz).....	45
Use of, in Spirit and Yeast Production. (Rothenbach).....	155
See also under Disinfectants.	
Antwerp, Import of Nitrate of Soda to. (T.R.).....	538
Apatite, Manufacture of Fertilisers from. (P) Wiborch.....	250
Apil. (Dulière and others).....	351
A New. (Cimicican and Silber).....	64
Aposafanine, Action of Bases on. (Fischer and Gieschen).....	1010
Aposafanine, Action of Phosphoric Chloride on. (Fischer and Hepp).....	1010
Apparatus. (Class I.).. 33, 128, 226, 315, 428, 522, 601, 650, 718, 785, 899, 1004	
Arabin in Diastase Prep., Occurrence of an. (Wroblewski) ..	1031
Arachis Hypogæa in Chocolate, Detection of. (Bilteyst).....	567
Arc Lamp, Slow Combustion. (Squire).....	385
Argentina: New Law as to Sale of Medicines. (T.R.).....	943
Argentol, Composition of.....	697
Aromatic Fluoro Compounds, Production of. (P) Valentiner. ..	821
Arrhenius, Importance of Analytical Chemistry in Ionic Dissociation Theory of. (Kuster).....	148
Arrow Poison from the Larva of the Beetle. (Boehm).....	570
Arsenic Acid, Exact Titration of. (Christensen).....	262
And Antimony, Detection of. (Conradson).....	518
And Sulphur of Australasia. (T.R.).....	478
And Vanadium, Separation of. (Field and Smith).....	164
Antimony, and Tin, Method of Separating. (Dancer).....	403
Antimony, and Tin, Qual. Separation of. (Rawson).....	113
Elimination of, from Copper. (P) Thomas.....	806
Estimation of, in Presence of Copper. (Heath).....	639
In Copper, Estimation of. (Holland).....	164
Manufacture of HCl Free from. (P) Wilde, Kynaston, and Brock.....	680
Manufacture of White. (P) Sims and Terrill.....	142
Output of, by England. (T.R.).....	351
Preparation of Reagents Free from. (Habermann).....	466
Separation of, from Antimony. (Piloty and Stock).....	754
Separation of, from Precious Metals. (Vavine).....	935
Some Soluble Compounds of. (Henderson).....	755
Volumetric Estimation of. (Szarvasy).....	164
Arthritic: A New Disinfectant.....	629
Arums, Active Principles of. (Hebert and Heim).....	758
Asafetida, Composition of. (Polasek).....	697
Asbestos Cells for Batteries. (P) Hawes.....	245
Fabric, Production of. (P) Klinger.....	796
Filtering Fabric, Manuf. of. (P) Germain and others.....	428
Manufacture of Acid-Proof. (Schrader).....	522
The Supply of. (T.R.).....	350
Ash in Vegetable Foods. (Niederstadt).....	1033
Asphalt, Analysis and Chemistry of. (Endemann).....	121
And Petroleum, Crude Deposit of. (Boulanger).....	432
Manufacture of Artificial. (P) Hannemann and Boisy.....	323
Testing Artificial. (Gary).....	701
Asphaltites of Utah, The Uinta and Uncompahgre.....	747
Asphaltum, Analysis of. (Peckham).....	124
Attenuation, Effect of Various Methods of Brewing on. (Petit) ..	58
Aurocyanhydric Acid, Precipitation of Gold from. (Christy) ..	332
Australia, Kieselguhr in. (T.R.).....	949
Phosphorus for. (T.R.).....	479
Sulphur and Arsenic of. (T.R.).....	478
Autoclave, Ultimate Organic Analysis under Pressure in an. (Hempel).....	260
Azonium Bases, Relations of, to the Safranines. (Fischer and Hepp).....	435

B

PAGE

Bacillus Fermenting Brain Infusions, Pure Culture of a. (Wood and Wilcox).....	510
Bacteria, Apparatus for Cultivating. (P) Pourmer.....	754
App. for Developing Pure Cultures of. (P) Bendixen.....	751
Fixation of Nitrogen by. (Boulhac).....	72
Of Lactic Acid, Raising Permanent Pure Cultures of. (P) Lake. From von Lorentz.....	254
Physiology and Morphology of Acetic Acid. (Seifert).....	1031
Bacterium, A New Acetic. (Zeidler).....	432
A New Vinegar. (Zeidler).....	626
In Rum. (Vely).....	636
Bahamas, Foreign Competition in the. (T.R.).....	538
Baking Powders, Manufacture of. (P) Dietrich.....	738
Balata Industry of Dutch Guiana.....	52
Balsam, Spurious Tolu. (Braithwaite).....	667
Balsams, Rational Examination of. (Dieterich).....	940
Resins, and Gums, Cold Treatment of. (Dieterich).....	829
Barium Aluminate and Sulphate, Prod. of. (P) Peniakoff.....	240
Aluminate, Obtaining Barium Hydrate and Alumina from. (P) Peniakoff.....	536
Hydroxy-sulphide, Extraction of Sugar by. (Feld).....	625
Hydroxy-sulphide, Recovery of. (P) Feld.....	691
Peroxide, Danger of Fire during Transport of. (Dupré).....	492
Peroxide, Sugar Refining by. (Ranson).....	625
Sroutium and Calcium, Separation of. (Rawson).....	113
Sulphate and Sulphate, Solubility of, in Sugar Liquors. (Weisberg).....	251
Sulphocyanide from Spent Oxide. (Hollbin).....	680
Thiosulphate for Standardising Solutions. (Mutnianski).....	357
Barley and Malt, Sugar and Starch Formation in. (Gruss).....	691
Germination of, with Restricted Moisture. (Day).....	1031
Influence of Drying on Germination of. (Behrend).....	549
Plant and its Carbohydrate Constituents, The Chemistry of the. (Cross and Bevan).....	252
The Cell wall Dissolving Enzyme of. (Reinitzer).....	817
Treatment of, for Alimentary Purposes. (P) Dunn.....	628
Barrels, Purification of Used. (P) Englehard and Yarnold.....	634
Treating with Glue Comp. (P) Howden. From Tyeiak.....	546
Bases, Coal-Tar. (Ahrens).....	131
Contained in Fusel Oil. (Bamberger and Eubner).....	253
Electrolysis of. (Lomanitsch and Jostschitsch).....	118
Of the Triphenylmethane Series, Constitution of. (Weil).....	131
Organic Use of Potassium-Bismuth Iodide in Preparing. (Jahns).....	554
Basil. Essential Oil of. (Dupont and Guerlain).....	352
Basilicum Oil Distilled in Grasse.....	557
Baths, Enamelling of Firelay. (P) Chiff.....	800
Batteries, Various:—	
Air-tight Leclanché. (P) Hentley and Germain.....	745
Dry Electric. (P) Schmidt.....	337
Electric. (P) Kirkpatrick Picard.....	744

COLOURING MATTERS AND DYES, VARIOUS—*cont.*

PAGE

Dyestuffs—*cont.*

For Wool, Violet Monazo. (P) Inray. From Farbwerke vormals Meister, Lucius, and Brüning	735
Lactic Acid as a Solvent for	1011
Manufacture of. (P) Lake. From Lepetit and others	456
Of the Indigo Series, Manufacture of. (P) Blank	731
Of the "Patent Blue" Series, Manufacture of. (P) Inray. From The Farbwerke vormals Meister, Lucius, and Brüning	1012
Of the Phthalone Series. (P) Inray. From The Basle Chemical Works Bindschelder	677
Polyazo, Cotton Brown. (P) Pitt. From Cassella and Co.	531
Primary Disazo Brown. (P) Pitt. From Cassella and Co.	675
Production of Black Polyazo. (P) Pitt. From Cassella and Co.	136
Researches on Patent Blue. (Fritsch)	39
Safranine Azo, Soluble in Water. (P) Inray. From The Farbwerke vormals Meister, Lucius, and Brüning	233
Synthetic, Manufacture of. (Paul)	730, 732
Yellowish-red, of the Phthalone Series. (P) Inray. From The Basle Chemical Works Bindschelder	676
Hydrolysis of certain. (Rosenstiehl)	132
Hydroxylamine Derivatives of Anthraquinone. (Schmidt and Gattermann)	135
Indigo Salt, Action of Light on Kalle's. (Kopp)	432
Indons, Note on the. (D'Andriani)	905
Indoxyl Acid Series, Comp. of, Manuf. of. (P) Blank	734
Isosorinduline, Conversion of, into Naphthophenosafranine. (Kehrmann and Schaposchinkoff)	793
Isosorindulines, Investigation of the. (Fischer and Hepp)	132
Macurin, Dyeing Properties of. (Schuett)	1011
Madder, History of. (Liebermann and Friedländer)	39
Monochloroamphor, Oxidising Action of. (Vittet)	728
Naphthacetyl, Constitution of. (Witt and Dedichen)	134
Naphthyl Ethers, Preparation of $\alpha$ -Amido- $\beta$ . (Paul)	671
Naphthylsulphonic Acid, Action of Nitrous Acid on 2,3. (Nietzki and Knapp)	232
Naphthol, Sulphonic Acids of $\alpha$ . (Friedländer and Taussig)	728
Naphthylamine, Preparation of $\alpha$ . (Paul)	433
Nitrobenzene, Action of Light on Solution of, in Sulphuric Acid. (Friswell)	671
Nitrobenzene, Fusion Point, Boiling Point, and Specific Gravity of. (Friswell)	671
Nitro-Derivatives, New Products from Aromatic. (P) Johnson. From The Badische Anilin und Soda Fabrik	608
Nitrosulphthalene, Preparation of. (Paul)	433
Nitro- <i>p</i> -phenylene Diamine, Investigation of $\alpha$ . (Bulow and Mann)	607
Nitro-phenol, Production of Para. (P) Ellis. From La Société Chimique des Usines du Rhône	40
Nitroso-Methylphenylamine. (Cloetz)	520
Nitrotoluene para-sulphonic Acid, Prod. of Ortho. (P) Ellis. From La Soc. Chimique des Usines du Rhône	40
Orcinol, Amido- and Methylamido- Derivatives of. (Hendrich)	520
Oxyazo Compounds and Triphenioxazine Derivatives. (Auwers and Rohrich)	607
Parabenzoyltriphenylmethane and its Derivatives. (Bourcet)	132
Paranitraniline Reil. (Liebermann)	294
Patent Blue, Constitution of. (Erdmann)	324
Phenolphthalein, Quinoid Derivatives of. (Nietzki and Burckhardt)	232
Phenylene Blue, Preparation of. (Paul)	433
Phenylene Diamine, Preparation of $\mu$ . (Paul)	433
Phenylphenazonium, Conversion of, into Phenosafranine. (Kehrmann and Schaposchinkoff)	33
Phthaleine. (P) Inray. From The Farbwerke vormals Meister, Lucius, and Brüning	137
Phthalic and Sulphophthalic Acids, Production of. (P) Johnson. From The Badische Anilin und Soda Fabrik	676
Pyrocatechin-Sulphonic Acid and Intermediate Products, Manufacture of. (P) Ellis. From La Soc. Chimique des Usines du Rhône	674
Rhamnazin, Investigation of. (Perkin and Martin)	607
Rosanilines, Conversion of <i>p</i> -Nitrodiamidodiphenylmethane into. (Prud'homme)	794
Rosindone, Action of Phosphoric Chloride on. (Fischer and Hepp)	1010
Saccharins: Colouring Matters derived from Saccharine. (Monnet and Ketschelt)	728
Saccharo-fluorescein, Production of. (P) Ellis. From La Société Chimique des Usines du Rhône	735, 795
Safranines, Constitution of. (Nietzki)	132
Sulphonic Acids of the Aromatic Series, Production of. (P) Newton. From The Farb. vormals Bayer and Co.	407
Sulpho Acids, Prod. of. (P) Read Holliday and others	1011
Sulphonic Acids of Alkyl Derivatives of Meta-amidophenolphthaleine. (P) From The Farbwerke vormals Meister, Lucius, and Brüning	233
Tartrazine, Constitution of. (Auschütz)	324
Tetramethyldiamidodiphenylcarbinol, Products of Action of, on Para- and Meta-sulphanilic Acids. (Snares)	608
Thiobenzophenone, Preparation of Pure. (Gattermann and Schulze)	134

Colours, Aluminium Bronze, Danger of Explosion and Fire from. (Kaiser)	551
Aluminium Bronze, Danger of Explosion and Fire from. (T.R.)	1053

Colours—*cont.*

Apparatus for Drying. (P) Sanderson	620
Coal-tar, in White Wines, Testing for. (d'Aguiar and da Silva)	361
Difference between Coal-tar, and Caramel. (d'Aguiar and da Silva)	361
For Water-colour Painting. (P) Reinhold	546
Of Pottery, Infl. of Furnace Atmosphere on. (Dumont)	611
Colza Mare, Adulteration of Linsed Meal and Mustard Flour with. (Jaworski)	267
Oil, Colour Reaction of. (Palas)	361
Combining Ribbons, Dyeing of. (P) Desmoulin	737
Combustibles, Carbonising, Charring, or Coking. (P) Basch and Grapel	902
Combustion in Furnaces, Means for Promoting. (P) Whitaker	902
Products, Utilisation of. (P) Cook	432
Composition for Branding Sheep, Bales, &c. (P) Potter	686
For Cleansing. (P) Muller	546
For Coating Ships, Tanks, &c. (P) Purse	924
For Making Pavements, &c. (P) Davies. From Frederick	681
For Making Pipe and other Joints. (P) Thompson	1017
For Printers' Inking Rollers. (P) White	924
For Making Tight Joints. (P) Redhead	916
Insulating, Weather, Acid, and Fire-resisting. (P) Stocker and Zander	924
Compound for Dressing Woven Fabrics. (P) Blumer, jun.	237
Compounds, Manufacture of Albuminous. (P) Inray. From The Farbwerke vormals Meister, Lucius, and Brüning	558
Manufacture of Pharmaceutical. (P) Newton. From The Farb-fabriken vormals F. Bayer and Co.	558
Production of Adhesive. (P) Boulh. From Higgins	625
Concentrating Apparatus for Acids. (P) Dyson	913
Concert, Smoking	509
Concrete, Badly Mixed	680
Manufacture of. (P) Robinson and Brookfield	443
Condenser for Steam-heated Pans. (P) Henderson	661
Condensers, Reflux. (Sudborough and Feilman)	979
Use of Aluminium for. (Norton)	465
Condensing Apparatus. (P) Merrick and Washburn	602
Column. (P) Hirsch	602
Congress of the Société Technique du Gaz en France	661
On Technical Education, International	579
Conium maculatum, Action of. (Findlay)	757
Maculatum, Pharmacy of. (Farr and Wright)	756
Cooling Apparatus. (P) Halpin, Allott, and Sterne	602
(P) Klein	601, 602
See also under Heating Apparatus.	
Copal, Zanzibar. (Stephan)	51
Copper Acetate, Production of. (P) Schmidt	611
Analysis of Commercial. (Murrain)	359
And Iron, Uniting or Welding. (P) Andrews	806
And Nickel, Separation and Recovery of. (Ulke)	262
Apparatus for Depositing, on Printing Rollers and the like. (P) Wylie and Grant	446
Apparatus for Refining, by Electrolysis. (P) Elmore	
From Elmore	338
As Sub-sulphide, Determination of. (Wegscheider)	562
Browning	918
Cadmium Analsam for Filling Teeth. (P) Rindler	47
Carbonate, Basic Preparation of. (Luckow)	744
Electrolytic Analysis of. (Holland)	66, 164
Electrolytic Production of, Direct from Ore	49
Estim. of Arsenic, Antimony, and Sulphur in. (Holland)	164
Estimation of Arsenic in Presence of. (Heath)	680
Glass Coloured by. (Zulkowski)	441
Impurities in Raw. (Schlagdenhauffen)	1019
In Bronze, Determination of. (Holland)	763
Iron Alloy, Manufacture of. (P) Baron	617
Liquors, Extraction of Zinc from Spent. (P) Wylie and others	444
Metallic, Elimination of Arsenic from. (P) Thomas	806
Nitrate, Separ. of, in Manuf. of Lunar Caustic. (Warden)	255
Obtainment of. (P) Noad and Azate	617
Ores, Treatment of. (P) Boulh. From Koehler	918
Oxide, Preparation of. (Luckow)	744
Phosphate, Basic Preparation of. (Luckow)	744
Precipitation of, by Acetylene. (Soderbaum)	562
Precipitation of Potassium Arsenioides by. (Christy)	333
Process for Extracting. (P) Thompson. From Sinding-Larsen	805
Production of Spain in 1896. (T.R.)	372
Quantitative Analysis of Commercial. (Hampe)	1043
Re-fining, Electrolytic, in the U.S.A. (Kruppa)	50
Removal of Oxide from Melted. (Kern)	335
Salts, After-Treatment of Azo Dyestuffs with. (Rumpf)	1011
Silver Group of Alloys. (Osmund)	614
Silases, Treatment of. (Ulke)	49
Smelting, Present Mode of. (Lang)	739
Solutions, Preparation and Purification of. (P) Graham	742
Sulphate, Prices of. (T.R.)	945
Sulphate, Production of. (P) Savage	738
Sulphide, Solubility of, in fused Alkali Poly-sulphides. (Prost and Van de Casteele)	827
Voltameter, Advantages and Disadvantages of the. (Foerster)	742
Zinc Couple for Determ. of Nitric Nitrogen. (Stock)	107
Coprah Oil, Edible Fat from. (P) Kuffin	50
Corks, Damagers occasioned by. (Will)	348

	PAGE
Corrosive Sublimates, Disinfecting Properties of. (Borchow).....	629
Cosaprine - A New Antipyretic. (Schwarz).....	631
A New Antipyretic. (Von Vamassy and Fonyvossy).....	1038
Cotton. (Class V.).....	11, 137, 234, 326, 437, 532, 603, 677, 786, 795, 907, 1012
Absorption of Magnesium and Aluminium Chlorides by. (Breind and Hanofsky).....	736
Bleaching. P. Kent.....	439
Cloth, Drying Moistened. (Witwicki).....	42
Fabrics, Printing with Indigo on. (Kurz).....	1014
Fabrics, Removal of Mineral Oil Stains from. (Pentecost).....	469
Fabrics, Use of Turpentine in Printing of. (Casanova).....	327
Fibres, Tendering of, by Acid during Sulphur Steaming.....	795
Machine for Dyeing. P. Ender and others.....	1014
Process for giving Silk-like appearance to. (P) Seyfert.....	796
Scraping Mercerised. (Werner).....	437
Seed Oil, American, in Marseilles. (T.R.).....	839
Seed Oil and Olive Oil, Behaviour of Mixtures of, in the Cold. (Goldberg).....	448
Seed Oil, Characteristic Reaction of. (Halphen).....	1045
Seed Oil, Prod. of Dyes from. (P) Marchlewski and others.....	539
Seed Oil, Separation and Purification of Colouring Matter from. (P) Wilson and Stewart.....	151
Stuffs, Prod. of Silk-like Effects on. (P) Inay. From The Farlow & Co.'s Meister, Lucius, and Brünig.....	1013
Substitute for Azurine Pink on. (Goldovsky).....	437
Waxes, Benzochrom Black for. (Heinrich).....	534
Waste, Apparatus for Decreasing. (P) Turney.....	677
Waste, Decreasing and Cleansing. (P) Turney.....	41
Waste, Recovery of Grease and Oil from. (P) Wright and Monk.....	41
Wool, Absence of Pentose Derivatives in. (Suringar and Tollens).....	168
Wool, Proportion of Pentosans in. (Suringar).....	167
Yarn, Aniline Black on. (Weise).....	796
Yarn, Recent Progress in Dyeing.....	533
Coumarin, Purification of. (Classen).....	352
Council for 1897-98.....	595
Report of.....	595
Cow Pea, Proteids of. (Osborne and Campbell).....	820
Copper-Coles Gold Recovery Process.....	803
Crape-like Designs on Vegetable Fabrics, Prod. of. (P) Weiss.....	258
Cream, Preservation of. (P) Higgins.....	457
Sterilising. (P) Fagersten and Korsell.....	60
Crematorium, Visit to the Manchester.....	596
Creosote, Preparations, Manufacture of. (P) Ellis. From La Société Chimique des Usines du Rhône.....	1038
Creosotes, Rapid Analysis of. (Adrian).....	266
Crucible for Steel Melting, Permeability of. (Arnold and Knowles).....	540
Crucibles, Assay of Ground Graphite. (Crosse).....	1041
Lining. (P) Piacet.....	919
Crystalline Materials, Method and Apparatus for Drying, Ac. (P) Sherratt and Richards.....	1005
Culiban Oil.....	556
Cupric Salts, Action of Acetylene on. (Soderbaum).....	569
Cuprous Oxide, Estimation of. (Caven and Hill).....	981
Curcumin, Production of. (Paul).....	731
Curcumin, Composition of. (Carmichael and Silber).....	231
Customs Decisions in France. (T.R.).....	643
Decision in Italy. (T.R.).....	269
Decisions in Switzerland. (T.R.).....	945
Decisions in the United States. (T.R.).....	269, 643, 945
Regulations.....	73, 399, 572, 643, 796, 769, 896
Regulations in the United States. (T.R.).....	707
Tariff of Canada, New. (T.R.).....	572, 856
Tariff of Cape Colony. (T.R.).....	769
Tariff of Victoria. (T.R.).....	837
Cutch, Preparation of.....	39
Preparing for Sale and Use. (P) Caruthers.....	258
Cyanide Bullion, Smelting and Refining. (Caldecott).....	503
Calcing Ores before Treatment with. (T.R.).....	1054
Mill Solutions. (Arzall).....	917
Process, Chemistry of the. (Bodlander).....	45
Process, Gold, Notes on. (James).....	804
Process, Gold, Prof. Christy on the. (Bottell).....	739
Process, Limitation of the. (Arzall).....	917
Solutions, Examination of Residual. (Ellis).....	115
Solutions, Precipitating Gold from. (Ehrmann).....	538
Solutions, Ppn. of Gold and Silver from. (P) James.....	339
Solutions, Solution and Ppn. of Gold in. (Christy).....	332
Treatment, Roasting previous to. (Macgregor).....	803
Cyanides, Apparatus for Manufacturing and Recovering from Coal-Gas. (P) Lewis and Crapps.....	758
Apparatus for Obtaining. (P) Maxim.....	338
Conversion of Nitrates into. (Kerp).....	736
Drying Alkaline. (P) Gilmi.....	914
From Blast-Furnaces, Obtaining. (P) McCosh.....	1029

Manufacture of. (P) Clarke and Irwin.....	448
Detonators. See also under Fuses and Explosives. For Railway For Signals. (P) Jenkins.....	1039
Developers. See also under Photographic. For Photographs. (Hauff).....	260
Photographic. (P) Clark. From Lembach and Schleicher.....	65
Dextrin and Starch, Manufacture of Compounds of, with Form- aldehyde. (P) Classen.....	460
Dextrins, Isolation of the. (Lintner).....	1028
Dextrose, Analysis of Commercial. (Stern).....	453
Solution, Density, and Cupric-reducing Power of. (Brown, Morris, and Millar).....	166
Diamine, Investigation of o-Nitro-p-Phenylene. (Bulow and Mann).....	607
Diamphidia locusta, Arrow Poison from the Larva of. (Boehm).....	570
Dianisidine, Preparation of. (Paul).....	63
-Disulphonic Acid, Preparation of. (Paul).....	63
Diastase, Action of Light on. (Green).....	549
Action of, on Starch. (Ling and Baker).....	154
Chemical Nature of. (Osborne and Campbell).....	155
Constitution of. (Wroblewski).....	1031
Examination of Products of Hydrolysis of Starch by. (Brown, Morris, and Millar).....	165, 166
Hydrolysis of Starch by. (Brown and Pickering).....	624
Hypothesis of a Saccharogenic, in the Beetroot. (Barbet).....	252
Preparations, Occurrence of an Arabin in. (Wroblewski).....	1031
Products of Saccharification of Starch by. (Petit).....	1028
Solvent Action of. (Sigmond).....	817
Uncertainty of the Guaiacum Reaction for Active. (Paw- lewski).....	639
Diazo Compounds, Stable. (Gassmann).....	324
Dichloronaphthalene, Conversion of 1:1' into 1:4'. (Arm- strong and Wynne).....	673
Dichloronaphthalene-3-Sulphonic Acid, Products of Hydro- lysis of 1:1'. (Armstrong and Wynne).....	673
Diffusion and Seum Washing, Limits of Loss in. (Pellet) ..	680
Juice, Acidity of. (Pamenko).....	452
Juice, Acidity of. (Pellet).....	623
Juice, Conditions of Inversion of Sugar in. (Pellet).....	623
Juice, Conditions of Inversion of Sugar of. (Jesser).....	451
Digestion, Effect of Coal-Tar Colours in Foods on. (Weber).....	158
Of Beetroot Pulp, Aqueous. (Pellet).....	153
Digestors, Construction of. (P) Kellner.....	696
Digitalis, Determination of Active Principles of. (Keller) ..	767
Dihydroxynaphthalene Sulphonic Acid, Prep. of 1:1'. (Paul).....	671
Dill Oil.....	556
Dimethylamidozobenzene, Addition of, to Margarin. (Par- theil).....	456
Dimethylphenylpyrazolone: Its Compounds with Phenols. (Patein).....	353
Dinitrofluorescein, Yellow Dyestuff from. (Reverdin).....	231
Yellow Dyestuff derived from. (Reverdin).....	434
Dinitronaphthalene, Manufacture of Colouring Matter from. (P) Johnson. From The Badische Anilin und Soda Fabrik.....	436
Dinitronaphthalenes, Formation of. (Gassmann).....	231
Dinner, Annual.....	597
Dioscorine: Toxic Alkaloid from Dioscorea Hirsuta. (Schnette).....	1037
Diphenetidine-disulphonic Acid, Preparation of. (Paul).....	63
Diphenylene Disulphide, An Isomer of. (Gevresse).....	673
Diphthalylethene, Research on. (Kaufmann).....	433
Disinfectant, Alcohol as a. (Epstein).....	931
Aromatic as a.....	629
Disinfectants. (Class XVIII.).....	59, 158, 350, 459, 552, 629, 695, 751, 821, 931, 1034
For Russia. (T.R.).....	575

For Production of Calcium Carbide. (P) Haddan, from Colberg and others.....	730
Furnaces, Apparatus for Burning Liquid Fuel in. (P) Sharp.....	720
Beds or Tests of Cupellation. (P) McGhie and Ballard.....	1020
Blast. (P) Gibbins.....	543
Chamber Addition to Blast. (P) Hutchinson.....	245
Clay for Tronch. (Seeger and Cramer).....	329
Construction of. (P) Wagner.....	438
Crucible. (P) Bickford.....	1020
Crucible Melting. (P) Kirkham.....	1020
Deoxidising. (P) Jones.....	683
Electric. (P) Benther.....	48
Electric. (P) Horry.....	1006
Electric. (P) Price.....	545
Electrical. (P) Abel, from Siemens and Halske.....	789
Electrical. (P) Boulé, from Patin.....	528
Electrical. (P) Patten.....	528
For Burning Lime, &c. (P) Stein.....	332
For Consuming and Deoxidising Air and Gases. (P) Smith.....	692
For Glass-melting. (P) Thompson, from Muhlig.....	612
For Manufacture of. (P) Radcliffe.....	330
For Production of Combustible Gas. (P) Kitson.....	321
For Treatment of Town Refuse. (P) Willoughby.....	62
Gas. (P) Fletcher, and Fletcher, Russell, and Co.....	666
Gas, and Muffles, Combined, for Enamelling. (P) Procece.....	738
Gas-Regenerative. (P) Johnson and Thompson.....	229
Generator. (P) Thompson, from Herwig.....	129
Hydrocarbon, for Consuming Smoke. (P) Fraipont.....	720
Lining. (P) Place.....	919
Means for Charging Blast. (P) Lewis.....	445
Means for Promoting Combustion in. (P) Whitaker.....	902
Metallurgical. (P) Platt.....	47
Metallurgical. (P) Schwalme.....	918
Method of Working Blast. (P) Thwaite and Gardner.....	806
Obtaining Cyanides, &c. from Blast. (P) McCosh.....	1020
Re-generator. (P) Hall.....	902
Re-generator, for Gas-Retort Settings. (P) Stevenson.....	902
Salt-Cake, Measuring the Temperature of. (Schuler).....	708
Siemens' Regenerative. (P) Svoboda.....	663
Temperature Determinations in Pottery.....	143
Using Light Hydrocarbons as Fuel. (P) Fletcher and Russell.....	606
Using Liquid Fuel, for Ores and Metals. (P) Pietraschewski.....	1020
Wall Accretions on Lead Blast. (Hes).....	242
Fuse or Quick-Match, Manufacture of. (P) Lynam.....	634
Fusel Oil, Bases contained in. (Bamberger and Einhorn).....	253
Fusibility, Abnormal, of Mixture of Alkaline and other Phosphates. (Le Chatelier).....	43
Fusions, Apparatus for. (Paul).....	630

## G

Galicia, Gold Mines of.....	538
Ozokerite Monopoly in. (T.R.).....	774
Gallie Acid, Action of, on Quinoline Bases. (de Coninck).....	765
Acid and Tannin, Action of, on Alkaloids. (de Coninck).....	639
Gallium, Occurrence of, in Cleveland Clay Ironstone. (Hartley and Rance).....	367
Galvanic Batteries. See Batteries.	
Element, Zinc-Carbon as a. (P) Abel, from Sedneff.....	508

	PAGE
Galvanising, Method of. (P) Heathfield and Rawson.....	147
Galvanoplastic Bath, Apparatus for Determining Quantity of Metal Deposited by. (P) Druce.....	803
Gamboze, Composition of. (Sassinari).....	248
Garbage, Disposal of, by the Merz System. (Pownall).....	752
Incineration of, and Recovery of Ammonia. (P) de Bonardi.....	1034
Garden Party at Councillor Frankenburg's.....	601
Party at Dr. Schunk's.....	595
Gas. (Class II.)..... 35, 129, 227, 316, 429, 522, 603, 661, 719, 787, 900, 1005	
Action of Sulphuric Acid on Coal. (Fritzsche).....	1005
Analysis Apparatus. (Bleier).....	406, 634
Analysis, Apparatus for. (Kent, Smith, and Towers).....	400
Analysis, Apparatus for Industrial. (Vignon).....	699
And Air, Incandescent Lighting with Mixture of. (P) Denayrouze.....	130
And Petroleum, Genesis of Natural. (Phillips).....	727
Apparatus for Ascertaining Quantity of any, in a Gaseous Mixture. (Arndt).....	935
Apparatus for Estimation of Sulphur in Coal. (Fischer).....	760
Apparatus for Manufacture of Carburetted Water. (P) The Economical Gas Apparatus Co. and Merrifield.....	525
Apparatus for Producing, from Liquid Hydrocarbons. (P) van Vriesland.....	525
Apparatus for Production of Carburetted Water. (P) Wheatley and Kros.....	321
Apparatus for Scrubbing and Purifying. (P) Hersey, Hulett, and Chandler.....	220
Appliances for Increasing Illuminating Power of. (P) Lavender and Tice.....	37
Application of Benzol for Enriching Coal.....	429
Capsules for Containing Compressed. (P) Calderwood.....	429
Carburetted Water, Method and Apparatus for Making. (P) Humphreys and Glasgow.....	720, 720
Carburetted Water, Method and Apparatus for Manufacture of. (P) Addicks.....	720
Carbureting. (Young and Glover).....	662
Carbureting, by Means of Benzene. (Hoyer).....	318
Carburene as an Enricher of Coal. (Davis).....	663
Coal, Apparatus for Recovering Cyanides from. (P) Lewis and Cripps.....	738
Coal, Use of "Manjak" in Manufacture of. (Pye).....	429
Combustion of Illuminating, in Gas Engines. (Haber and Weber).....	227
Combustion of, in Contact with Cooled Surfaces. (Haber and Weber).....	316
Composition and App. for Enriching. (P) Stephenson.....	606
Congress of French Technical Society of.....	661
Determination of Free Nitrogen in Purified Coal. (Arth).....	470
Drying and Expansion of. (P) Arter.....	605
Engines. See under Engines.	
Enrichment of Coal. (Holgate).....	523
For Domestic Lighting, Value of. (Lewes).....	227
For Lighting and Motive Power, Method and Apparatus for Production of. (P) Kremer.....	720
For Lighting, Heating, &c., Treatment of. (P) Oving.....	721
From Hydrocarbon Oils, Production of. (P) Middleton.....	35
From Hydrocarbons, Apparatus for Producing. (P) Thompson, from Julien.....	903
From Liquid Combustible Materials, Method and Apparatus for Producing. (P) Tresenreuter.....	322
Furnaces for Production of Combustible. (P) Kitson.....	321
Generators. (P) Hemmesey.....	663
Inciting Appliances, Automatic. (Drehschmidt).....	603
Illuminating, Manufacture of. (P) Young and others.....	789
Industry, By-products of the. (Bunte).....	661
Light, Theory of Incandescent. (Hohmann).....	789
Lighting, Bodies for Incandescent. (P) Barriere.....	36
Lighting, Incandescent. (P) Denayrouze.....	321
Lights, Incandescent. (P) Hollins.....	321
Liquor, Estimation of Total Ammonia in. (Donath and Pollak).....	936
Liquor, Separ. Cyanogen Compounds from. (P) Bower.....	129
Mains, Stoppages in, due to Naphthalene. (Hoffmann).....	227
Manuf. Naphthalene in Modern. (Young and Glover).....	662
Manufacture of Combustible. (P) Denayrouze.....	36
Manufacture of Illuminating. (P) Lewes.....	430
Manufacture of Substances for Imparting Odour to. (P) Straube.....	526
Manufacture of Water. (P) Goldschmidt and Dellwik.....	525
Method and App. for Carbureting. (P) Bauwernerts.....	903
Method and Apparatus for Manufacture of. (P) Newburn, from Bates.....	431
Method and Apparatus for Manufacture of. (P) Wise, from Thomson.....	605
Method and App. for Prod. of Water. (P) Dellwik.....	431
Method and Apparatus for Removing Gaseous Iron Compounds from. (P) Straube.....	664
Method and Composition for Manuf. of. (P) Stephenson.....	604
Method of Burning very Rich. (P) Wigham.....	230
Natural, and Petroleum, Genesis and Chemical Relations of. (Sadtler).....	727
Oxygen in Illuminating, Determination of. (Pfeiffer).....	635
Processes, Comparison of Fuel. (Slocum).....	420
Producer, and Water, Method and Apparatus for Manufacture of. (P) Whitfield.....	605
Product Plant, Application of the Mond. (Humphrey).....	522
Producers, Method of Working. (P) Bommelmanns.....	130
Producers, Safety Devices for. (P) Humphreys and Glasgow.....	130
Production and Use of Water. (Dicke).....	900

Gas—cont.	PAGE	Glass—cont.	PAGE
Production of, from Air and Liquid Hydrocarbons, (P) van Vriesland.....	130	Containing Silver, Surface Lustre on, (Zsigmondy).....	1015
Purification, Experiments on, at Luton.....	679	Decorations on Graded Dull Frosted.....	1016
Purification, Use of Air with Lime for, (Carpenter).....	318	Devitrification of, for Manufacture of Ceramic Stone Objects, (P) Garchey.....	339
Purifying Materials, Thiocyanides from Spent, (Hollblum).....	35	Elasticity of, (Winkelmann).....	314
Recovery of Benzene from Coke-Oven, (Heinzelmung).....	632	Etching Plates, Production of, (P) Lohle.....	612

Tap, Automatic, (Michaels).....	105	Making, Aluminium in, (Aigert).....	43
Treating Peat and Coal for Obtaining, (P) Meikle.....	526	Making Sheets, German and Belgian Methods of.....	330
Treatment of Illuminating, (P) Batley.....	431	Manufacture of Sulphates, (P) Goerisch.....	680
Vessels or High-pressure Reservoirs, (P) Tyler.....	316	Materials for Clear.....	144
Gases and Liquids, Apparatus for Reducing Pressure of, (P) Matchett.....	602	Melting Furnaces or Troughs, (P) Thompson, From Mühlig.....	612
And Liquids, Condensing Column for, (P) Hirzel.....	602	Metallic Decorations on, (P) Kunze.....	44
Apparatus for Absorption of, in Liquids, (P) Hirzel.....	809	Oven for Fusing Designs, &c., on, (P) Albrecht.....	330
Apparatus for Electrical Treatment of, (P) Benner, Le Royer, and van Berchem.....	684	Pots and Trough Furnaces, Clay for, (Seger and Cramer).....	320
Apparatus for Generating Hydrocarbon, (P) Blakeley.....	230	Pottery and Enamels, (Class VIII.).....	43, 113, 329, 441, 537, 611, 680, 738, 799, 914, 1015
Apparatus for Measuring Pressure of Powder, in Gun Barrels, (P) Volam.....	1040	Production of Coloured Pictures, &c., on, (P) Albrecht.....	799
Apparatus for Purifying, (Vandeveldt).....	761	Proportions of Constituents of, (Hohlbaum).....	43
Apparatus for Recovering Benzene from, (P) Marks, From La Compagnie pour la Fabrication des Compteurs a Gaz.....	728	Refining Mineral Oil with Water, (Miedler).....	1000
Apparatus for Separation of Mixed, (P) Hampson.....	315	Rough-Etching Plate.....	143
Apparatus for Treating Solid and Pasty Substances with, (P) Mond.....	34	Sheet, Melting.....	1016
Chambers for Combustion of, (P) Hartmann.....	431	Sheets and Cylinders, Manufacture of, (P) Sievert.....	612
Cylinders for, (P) Lawson and Prescott.....	602	Trade of Bavaria, Decline in the, (T.R.).....	770
Dissolved in Liquids, Apparatus for Collecting, (Clowes).....	210	Tubes, Apparatus for Simultaneously Heating and Shaking in Sealed, (Fischer).....	699
Filter for Impregnating Liquids with, (P) Raydt.....	33	Water, and By-products, Manufacture of, (P) Prople.....	611
From Coke Furnaces, Treatment of.....	429	Window, in Turkey, (T.R.).....	271
From Electric Furnace Reactions, Furnace for Collecting, (P) Renzoli and others.....	231	Glassware, Decorating and Colouring Hollow.....	537
From Explosives, Measuring Power and Volume of, (P) Lake, From The Sprengstoff Actiengesellschaft Carobont.....	261	Glassworks Fine-Dust, Composition and Origin of, (Grosse).....	914
From Iron Blast Furnaces, Utilisation of, (P) Thwaite and Gardner.....	806	Glaze on Ceramic Ware, Cracking of, (Le Chatelier).....	44
Generator, Condenser and Holder for, (P) Bean and Ringwood.....	537	Glazes and Enamels, Part Played by Boric Acid in, (Grenet).....	144
Generator for, (P) Fernand des Essards.....	527	Coloration of Porcelain and Stoneware, (Recht).....	44
In Canned Goods, Collecting and Analysing the, (Doremus).....	1046	Globulin, Effect of Minute Quantities of Acid on, (Osborne and Campbell).....	820
Method and Apparatus for Detecting Noxious, (P) Mayer and Bush.....	162	Glove Kid, Tanning.....	686
Method and Apparatus for Generating, (P) Thwaite.....	525	Glover Towers, Construction of, (P) Jensen, From Lunge and Rohrmann.....	537
Method and Apparatus for Purifying, (P) Theisen.....	231	Towers, Construction of, (P) Jensen, From Rohrmann and Niedenfuhr.....	537
Obtaining Alkaline Salts from, Method and Apparatus for, (P) Craig.....	328	Towers, Construction of, (Niedenfuhr).....	912
Utilisation of Coke-oven.....	900	Glucina, Properties of Pure, (Lebeau).....	72
Valve for Cylinders Containing, (Duret et Lejeune).....	33	Glucose, Analyses of Commercial &c., (Stern).....	453
Gasworks Houses, Contamination of Air in, (Drehschmidt).....	752	And Sugar in Beetroot, Influence of Nitrogen on Proportions of, (Urban).....	690
Visit to the Manchester Corporation.....	596	Direct Production of, (Lippmann).....	621
Gay-Lussac Towers, Construction of, (P) Jensen, From Lunge and Rohrmann.....	537	Or Sugar, Manufacture of, (P) Bauer.....	750
Gelatin in Glue and Glue Liquors, Volum. Estim. of, (Jean).....	344	Glue, (Class XIV.).....	52, 152, 248, 340, 450, 516, 620, 686, 816, 1225, 1025
Plates, Etching Process for, (Moses).....	560	Compounds, (P) Howden, From Tyciak.....	516
Colloids, Preparation of Soluble, (P) Mills.....	622	Determination of Viscosity of, (Eels).....	264
Gelatinoid and Protein Substances, Determination of, (Allen and Seale).....	1047	Preparation of Liquid Casein, (P) Bolder.....	1026
Generators, Method of Using Calcium Carbide in, (P) Smith.....	790	Volumetric Estimation of Gelatin in, (Jean).....	364
"Geosote": Guaiacol Valerianate, (Rieck).....	632	Waterproof, Manufacture of, (P) Gardner.....	749
Germanium Essence, Researches on, (Charabot).....	555	Gluten, Method and Apparatus for Production of, (P) Keil.....	927
German Chemical Industrial Society, Annual Meeting of, (T.R.).....	840	Glycerin and Ethyl Alcohol, Determination of, (Nieloux).....	566
Germany and Britain, Drug Trade between, (T.R.).....	837	Concentration of, (P) Rich.....	619
Basic Slag in, (T.R.).....	477	Estimating Small Quantities of, (Nieloux).....	565
Beet-Sugar Returns of, for 1895-96, (T.R.).....	574	Estimation of, (Bordas and de Raczowski).....	167
Chemical Profits of, (T.R.).....	645	In Sweet Wines, Determination of, (Fabris).....	830
Chemical Trade of, (T.R.).....	272	In Wine, Determination of, (Boettlinger).....	1048
Crisis in Sugar Production of, (T.R.).....	574	In Wine from Grapes affected with Sweet Rot, (Laborde and Raczowski).....	1031
Drawback on Spirits in, (T.R.).....	478	Quantitative Estimation of, (Bullheimer).....	252
Effects of the New Sugar Tax in, (T.R.).....	477	Glycerophosphates, Preparation of, (Delage).....	553
Importance of Calcium Carbide Industry to, (Frank).....	663	Glycoylactic Acid and its Successive Decompositions, Kunz-Krause).....	832
Leather Industry in, (T.R.).....	476	Gold, Absence of, from Granite Rock of Bald Mountain, (Smith).....	46
Mineral Production of, in 1896, (T.R.).....	478	Accumulation of, in Slimes, (Caldcroft).....	804
Mining and Metallurgical Industries of, (T.R.).....	571	Action of Phosphorus on, (Granger).....	474
Molasses and Peat Fodder in, (T.R.).....	1028	Action of Potassium Zinc Cyanide Solutions on, (Sharwood).....	1018
New Margarine Law of, (T.R.).....	708	Amalgamating and Extracting from Dry-crushed Ore, (P) Oppermann.....	335
Production of Iron Ore in, (T.R.).....	172	And Silver in Minerals, Estimation of, (Truchot).....	66
Proposed Tax on Distill. Products of Wood in, (T.R.).....	374	And Silver, Recovery of, from their Solutions, (P) Gopner and Diebl.....	742
Returns of Patents Office of, for 1896, (T.R.).....	272	Apparatus for Amalgamation of, (P) Oppermann.....	147
Silk Weighing in, (T.R.).....	532	Apparatus for Extraction of, (P) Johnson, From Deebie.....	147
Trade Returns of, for 1896, (T.R.).....	270	Apparatus for Recovery of, (P) Vivian.....	444
Gilding Solutions, Assay of, (Allen).....	828	Apparatus for Separating, from other Metals, (P) Hyatt, Chemistry of the Cyanide Process of Extracting, (Eodlander).....	805
Ginger, Essence of, (Glass).....	551	Cyanide, Solution and Precipitation of, (Christy).....	45
Examination of Commercial, (Glass).....	551	Cyanide Process, Notes on, (James).....	804
Gland, Production of the Active Constituents of the Thyroid, (P) Murray.....	633	Detection of, in Sea Water, (Sonstadt).....	46
Glass, Artificial Stone from Broken.....	44	Electric Precipitation of, from its Cyanide Solutions, (P) James.....	339
Calculation of Yield of a Charge of, (Hohlbaum).....	149	Electro-Deposition and Recovery of, (Androsoli).....	96
Coloured by Copper, (Zulkowski).....	441	Electro-Deposition of, (P) Andreoli.....	150
Coloured by Direct Penetration of Metals or Salts, (Lemal).....	611	Estimation or Extraction of, (Serrant).....	334
Colouring, with Silver, (Zsigmondy).....	1015	Extraction, By-Products from, (Butters).....	1018

Methane, Tetraphenyl. (Gombosi)	942
Methoxy-azobenzene-disulphonic Acid, Prep. of. (Paul)	65
Methyl Iodide, Action of, on certain Col. Mat. (Rosenstiehl)	132
Methylated Spirit in India. (T.R.)	272
Methylbenzene Sulphonic Anhydride, Manuf. of. (P) Savigny	759
Methylene, Preparation of. (Sudborough)	408
Methylheptanone, Preparation of. (Verley)	351
Metal Developer, Effect of Thiosulphate in. (Hauff)	559
Production of. (Paul)	963
Mexican Imports of Chemical Products. (T.R.)	838
Mexico, Beer of. (Lang)	549
Exports of Chile from. (T.R.)	838
Micro-Organisms: Their Effect and Influence in Chemical Industries. (Schack-Sommer)	196
Milk, Aeration and Preservation of. (P) Nash	930
Albuminoids of Cows. (Storch)	627
And Cream, Sterilising. (P) Fagersten and Kossell	60
Apparatus for Sterilising. (P) Brouhead. From Dierks and Mollmann	60
Cause of Coagulation of Heated. (Fardache)	628
Detection and Determination of Boric Acid in. (Denigès)	766
Detection of Formalin in. (Jorissen)	1045
Estimation of Fat in. (Fresenius)	366
Occurrence of Alcohol in. (Weller)	1033
Preparation of a Food Product from. (P) Bernstein	930
Preservation of. (P) Higgins	457
Preservation of, by Partial Freezing. (Jeun)	1032
Preserving. (P) Murray	752
Reagents Distinguishing between Raw and Boiled. (Dupouy)	828
Sterilisation of. (P) Yause	628
Tablets, Production of. (P) Horiack	930
Treating, to Render Suitable for Infants' Food. (P) Baekhaus	694
Utilisation of "Separated." (P) Higgins	752
Millboard for Bobbins	754
Milling with Aet's	139
Millstones, Manufacture of Artificial. (P) Theiner	429
Mineral Industry of Bosnia-Herzegovina in 1896. (T.R.)	772
Oil Stains, Removal of, from Cotton Fabrics. (Pentecost)	499
Oil used in Bread-Making. (Hanemann)	60
Output of the United States. (T.R.)	768
Production of Canada. (T.R.)	270
Production of Germany in 1896. (T.R.)	478
Production of Spain in 1896. (T.R.)	571
Production of the United States, 1896. (T.R.)	75
Products of the United Kingdom. (T.R.)	839
Resources of Wyoming. (T.R.)	377
"Mineral Soap." (Knight)	705
Mineral Waters. See under Waters.	
Minerals, Estimation of Gold and Silver in. (Truchot)	406
Spectrographic Analysis of Stassfurt. (Hartley and Ramage)	243
Mines and Quarries of United Kingdom, Statistics of, for 1896. (T.R.)	830
Electric Lamp for Controlling the Air in. (P) Cohn	231
Minet's Aluminium Process	48
Mining and Metallurgical Industries of Germany. (T.R.)	574
Mint Oils. (Duyk)	159
Mites, Presence of, in Wine. (Mathieu)	818
Mixing Apparatus. (P) Alexander	1005
Mixtures, Electrolysis of. (Schuder)	744
Moisture, Absorption of, by Deliquescent Substances. (Hake)	704
Molasses, Analysis of. (Loisac)	68
And Beet Pulp, Manuf. of Fodder from. (Wustenhäuser)	154
And Peat Fodder in Germany	1028
Clarification of Solutions of, for Inversion. (Neumann)	68
Commercial Analysis of. (Molhan)	830
Determination of Specific Gravity of. (Boet)	315
Extracting Sugar from, by Baryta. (Langen)	152
Extraction of Sugar from. (P) Feld	251, 625, 691
Incipient Carbonisation of. (Crawley)	927
Of Raw Beet Sugar, Production of Fodder from. (P) Hensel	252
Purification of. (Kastengren)	452
Raffinose in Cane. (Pellet)	688
Molybdenum and Chromium, Alloys of Steel with	146
As a Wool Mordant. (Knecht)	977
Preparation of Pure. (Guichard)	822
Steel, Properties of. (Von Lupin)	1017
Volumetric Estimation of. (Friedheim)	293
Molybdic Anhydride, Reduction of. (Guichard)	822
Monazite. (Nitzé)	755
In Idaho. (Lindgren)	755
Sands, Examination of Earth contained in. (Schützenberger and Boudouard)	429
Sands, Process for Enriching. (P) Buldens	824

Montana, Occurrence of Tellurium in. (Leone)	242
Mordant, A New Chrome. (Anand)	805
For Cotton, Chromium. (Knecht)	574
Mordants, Ammonium Phosphate for Fixation of. (Knecht)	527
Colouring Matters Dyed on Nineteen Metallic. (Scheller and Boylusk)	951
Tungsten and Molybdenum as on Wool. (Knecht)	677
Mordanting Agent and Method for Vegetable Fibres. (P) Boehringer Sohn	747
Morocco, Chemicals in. (T.R.)	848
Morphine and Codeine, A Solvent permitting Separation of. (Fouquet)	179
La Opium, Assay of. (Grandval and Lapoux)	265
Mortar, Examination of Old. (Garry)	1017
Influence of Sea Water on. (P) Fontenay	339
Manufacture of Fire-proof. (P) Fontenay	916
Usability of Sugar-Works Sediment for Making	681
Mortars. (Class IX.)	14, 111, 240, 339, 442, 538, 612, 680, 738, 800, 915, 1016
"Mosaic Gold," Preparation of. (Lazutti)	922
Mass-Litter Manure, Obtaining Products from. (P) Van der Griendt	547
Mother-of-Pearl, Substitute for. (P) Cabot	449
Motor, Laboratory Water. (Tryller)	824
Mould, A New: "Eupiptis Gayon." (Laborde)	102
Fermentation. (Emmerlich)	348
Mousseline de Laine, Prod. of Crimp Patterns on. (Knecht)	150
Muffles and Gas Furnaces combined, for Enamelling. (P) Prece	758
For Annealing Metals. (P) Elkington and Co. and Fellows	616
Munich Beer, Analysis of. (Domens)	559
Museum at Hong Kong, Technical. (T.R.)	374
Musk, Artificial, and its Nitro Derivatives. (Balobrzsko)	823
Manufacture of Artificial. (P) Baile	559
Manufacture of Artificial. (P) Imray. From The Fabriques de Produits Chimiques de Thanu et de Mulhouse	559
Manufacture of Substitutes for Natural. (Dinesen)	278
Pouches, Detec. of Adulterated, by Röntgen Rays. (Wolff)	266
Production of Artificial. (P) Mackenzie. From Schmid	257
Mustard Flour, Adulteration of, with Colza Marc. (Jaworski)	297
Mydrol: Iodomethylphenyl Pyrazolone	400
Myriobolans, Apparatus for Treating. (P) Smithson	737
Myrrh, Composition of Bisobol. (Tucholka)	948
Distinction of Bisobol, from Official. (Tucholka)	948

## N

Naphacetyl, Constitution of. (Witt and Dedichen)	134
Naphthalene in Modern Gas Manufacture. (Young and Glover)	662
Stoppage in Gas Mains due to. (Hoffmann)	227
Sulphonic Acid, Preparation of 1,1'-Dihydroxy. (Paul)	671
Naphthalene, Heavy, and their Treatment. (Charitschkow)	38
Naphthalenes, Formation of, by Distillation of Fats under Pressure. (Engler and Lehmann)	1049
Naphthohydroquinone, Production of. (Paul)	773
Naphthol, Azo Dyestuffs from $\alpha$ , and $\alpha$ -Naphthylamine Sulphonic Acids, Constitution of. (Gattermann and Schulze)	232
Derivatives, Manuf. of Para-amido- $\beta$ . (P) Wit	755
Estimation of $\alpha$ , in Commercial $\beta$ -Naphthol. (Prochazka and Hermann)	891
Ethers, Preparation of $\alpha$ -Amido- $\beta$ . (Paul)	671
Reaction Distinguishing $\alpha$ , from $\beta$ . (Leger)	688
Sulphonic Acids of $\alpha$ , (Friedlander and Tausig)	728
Use of Nitroso- $\beta$ , in Inorganic Analysis. (Barnes)	67
Naphthophenosafranine, Conversion of Is-resnaldine into. (Kehrmann and Schaposchinkoff)	793
Naphthylamine, Preparation of $\alpha$ . (Paul)	923
Sulphonic Acids, Constitution of Azo Dyestuffs from $\alpha$ -Naphthol and $\alpha$ . (Gattermann and Schulze)	292
Negrotyp Process, Itt-rehm's. (Fisch)	590
Neroli, Essence of. (Duyk)	159
Netherlands: Regulations as to Methylated Spirits. (T.R.)	74
Removal of Duty on Aniline Oil in. (T.R.)	616
Newfoundland, Foreign Competition in. (T.R.)	838
Petroleum in. (T.R.)	910
New-Guinea Nuts. (Spiegel)	169
South Wales, Platinum in. (T.R.)	666
Niacara, Chemical Plant at. (T.R.)	73
Falls, Carborundum at. (Fitzgerald)	243
Nicaragua, Carboléum in. (T.R.)	643

Sensitive Reaction for. (Riezler) .....	699
Nitrobenzene, Action of Light on Solution of, in Sulphuric Acid. (Friswell) .....	671
Electrolytic Reduction of. (Loh) .....	744
Fusion Point, Boiling Point, and Sp. Gr. of. (Friswell) .....	671
Nitrobenzol, Behaviour of Indigo in. (Gerland) .....	108
Nitrobenzylamine, Manufacture of <i>o</i> - and <i>p</i> -. (P) Lury. From Farberwerke vorm. Meister, Lucius, and Bruning .....	795
Nitrocellulose, Manufacture of. (P) LaBeck .....	760
Manufacture of Compositions containing. (P) Justice, From The Marsden Co. .....	815
Solvents for. (P) Strechebert .....	907
Treatment of, for Coating Fabrics. (P) Sutherland and McLaren .....	1013
Nitro Derivatives, New Products from Aromatic. (P) Johnson. From The Badische Anilin und Soda Fabrik .....	608
Nitr. 4-amidodiphenylmethane, Conversion of <i>ps.</i> into Rosanilines. (Prof. Hume) .....	794
Nitrogen and Carbon in Organic Compounds, Estimation of. (Fritsch) .....	71
Apparatus for Fixing. (P) Maxim .....	338
Chloride, Action of Solvents on. (Heutschel) .....	628
Combustion of. (Beier) .....	639
Determination, Source of Error in Kjeldahl's. (Sjollena) .....	1045
Different Forms of, in the Beetroot. (Urban) .....	690
Fixation of, by Algae and Bacteria. (Bouillag) .....	72
In Cheese, Estimation of. (van Ketel and Antusch) .....	906
In Purified Coal-Gas, Determination of Free. (Arth) .....	470
Nitroglycerin Explosives, Manufacture of. (P) Bichel .....	934
Manufacture, Denitrating Acid Used in. (P) Kynoch and Co., and Coking .....	825
Manufacture, Mixing and Conveying Acids for Use. (P) Kynoch and Co., and Coking .....	934
Manufacture, Treating Spent Acids from. (P) Kynoch and Co., and Coking .....	1040
Toxic Power of. (Bokorny) .....	61
<i>See also under Explosives.</i>	
"Nitrogerate." (Pauli) .....	1021
Nitromethoxybenzene- <i>p</i> -sulphonic Acid, Prop. of <i>o</i> -. (Paul) .....	63

	PAGE
Nitronaphthalene, Commercial Prep. of. (Krug and Blomen) .....	933
Preparation of. (Paul) .....	433
Nitrophenol, Preparation of <i>p</i> -. (Paul) .....	63
Nitrophenol, Ortho- and Para-, and their Technical Uses. (Paul) .....	62
Production of Para-. (P) Ellis. From La Société Chimique des Usines du Rhône .....	40
- <i>p</i> -Sulphonic Acid, Preparation of <i>o</i> -. (Paul) .....	63
Nitrosomethyl-diphenylamine. (Clorz) .....	529
Nitrotoluene-para-sulphonic Acid, Prod. of Ortho-. (P) Ellis. From La Société Chimique des Usines du Rhône .....	40
Nitrotoluidines, Production of Orange and Red Shades on $\beta$ -Naphthol Ground by Means of. (Skawinski) .....	438
Nitrous Acid, Action of, on 2,3-Naphtholsulphonic Acid. (Nietzki and Kuapp) .....	232
Acid, Apparatus for Condensing. (P) Debell .....	737
Acid, Colorimetric Estimation of. (Riezler) .....	638
Acid, Delicate Reaction for. (Riezler) .....	261
Njalla Bean. (Spiegel) .....	160
Nobel's Bequest to Science, Dr. (T.R.) .....	72
Non-Magnetic Material, Magnetic Concentration of. (Darby) .....	971
Northberg Coke-Oven Plant, The. (T.R.) .....	950
Norway, Cellulose and Wood-Pulp Industry of. (T.R.) .....	1053
Clevite found in. (T.R.) .....	268
Notes. General Trade .....	73, 172, 271, 371, 477, 575, 645, 708, 772, 810, 945, 1053
Laboratory. (Stock) .....	107
Scientific and Technical .....	72, 168, 266, 367, 474, 569, 642, 704, 767, 831, 941, 1050
Notices, Official ... 1, 85, 181, 281, 383, 489, 583, 637, 718, 783, 851, 960	
Nottingham Section, Chairman's Address to. (O'Sullivan) ...	977
Nucleus, Preparation of, and Manuf. there of. (P) Carrick .....	933
Nuts, Composition of Kola .....	606

O

Obituary Notice: Doulton, Sir H. ....	899
Fresenius, Dr. C. Remigius .....	521
Hart, Peter .....	521
Kunheim, Hugo .....	315
Meyer, Victor .....	789
Schutzenberger, Paul .....	613

Spirit, <i>cont.</i>	
Method and Apparatus for Producing Gas from, (P) Tresenreuter	322
Production of Woods, (Klar)	732
Production of Use of Antiseptics in, (Rothenbach)	135
Use of, for Incandescent Light, (Hayduck)	575
Ants, Cleaning Large	234
Spirits, (Class XVII.)	57, 154, 252, 344, 438, 548, 625, 691, 750, 817, 928, 1029
Apparatus for Removing Impurities from, (P) Bennett	549
Denaturing of	544
Drawback on, in Canada, (T.R.)	644
Estimation of the Higher Alcohols in, (Rogues)	1045
Means for Improving, (P) May and Newlands	550
Meter for, (P) Chapp	733
Spruce, Oil of	1036
Squibb's Method for Estimating Acetone, Improvement of, (Kehler)	509
Stain for Wood, (P) Junghans	924
Stannic Sulphide, Preparation of Crystalline, (Lacotte)	922
Stannous Chloride, Preparation of, (Vignon)	13
Iodide, Action of Light in Crystallisation of, (Warden)	247
Star Anise, Cultivation of, in China, and Distilling Oil from, (Anise Oil, Adulterated with Petroleum, (Umney)	1056 1055
Starch, (Class XVI.)	55, 152, 250, 342, 451, 547, 622, 687, 749, 816, 927, 1027
Action of Diastase on, (Ling and Baker)	154
Albuminoids in Substances Rich in, Estimation of, (Trybl)	244
And Dextrin, Manufacture of Compounds of, with Formaldehyde, (P) Classen	459
And Starch Solution, Preparation of Soluble, (Foerster)	254
Conditions affecting Volumetric Estimation of, (Littleton)	264
Control of Manufacture of, (Heber)	623
Estimation of, in Frozen Potatoes, (Sauer)	365
Examination of Products of Hydrolysis of, by Diastase, (Brown, Morris, and Millar)	165, 166
Fermenting Moulds, Comparative Energy of, (Sannametto)	626
Fixation of Iodine by, (Rouvier)	475
Formation in Barley and Malt, (Grüss)	691
Formation, Observations on, (Bokorny)	154
Hydrolysis of, by Acids, (R-dle and Deffen)	167
Hydrolysis of, by Diastase, (Brown and Pickering)	624
Manufacture, Digestibility of certain By-products of, (Schulze)	829
Manufacture of, (T.R.)	842
Manufacture, Organisms in, (Sauer)	547
Method and Apparatus for Production of, (P) Keil	927
Potato, (Sauer)	623
Products, Estimation of Total Carbohydrates in Acid hydrolysed, (Ruffe and Faxon)	1048
Products of Saccharification of, by Diastase, (Petit)	1028
Soluble, (Syniewski)	1029
Soluble, (Wroblewski)	1028
Solvent Action of Diastase on Ungranulated, (Scheidt)	1028
Specific Rotation of Soluble, (Brown, Morris, and Millar)	164
Transformation by Sulphur Dioxide, (Berzel)	548
Starches, Chemistry of the, (Littner)	1028
Starching Prep., and Manufacture thereof, (P) Ansoerg	928
Stassfurt Minerals, Spectrographic Analysis of, (Hartley and Ramage)	243
Steam and Chlorine, Action of Mixture of, on Glowing Charcoal, (Naumann and Mündorf)	449
Apparatus for Superheating, (P) Sinclair	428
Distillation, Apparatus for, (Matthews)	359
Gas, and Electricity as Sources of Energy, (Howan)	975
Generating Vessels, Conveying Heat to Contents of, (P) Martin and Stapley	719
Highly Superheating Wet, (P) Schmidt	55
Method and Apparatus for Producing Superheated, (P) Adorian	428
Pipes, Zinc Plates as Covering for, (Rüssner)	718
Plant, Leaks in, (P) Delapine	1030
Sterilising Apparatus, (P) Delapine	1032
Superheated, (Ripper)	718
Volatilisation of Lactic Acid by, (Muller)	107
Steamers for Wood, Destruction of Flame Bolts in	695
Steaming, Method of, (P) Hargreaves	1004
Stearic Acid, Determination of Unsaponified Fat in, (P. and J. Jean)	344
Stearin in Spermaceti, Detection of, (Hirschelshin)	639
Stearine, Bleaching of, (Ramboel)	159
Stearolactone, Transformation of Oleic Acid into, (David)	339
Steel, Alloys of, with Molybdenum and Chromium	145
And Iron, Carbonising, (P) Wilson and Stubbs	544
And Iron, Manufacture of, (P) Boulton, From Otto	244
And Iron, Production of Alloys of, (Piacet)	147
Annealing of, (P) Dalzell and Fairley	806
Apparatus for Determination of Sulphur in, (Mende)	934
Bertrand-Thiel Process for Production of, (Gilehrst)	243
Carbide in, (Mylius, Foerster, and Schoene)	115
Crucible, Manufacture of, (P) Danner	919
Diffusion of Sulphides through, (Campbell)	801
Direct Production of, from Ore, (P) Searls and Gredt	47
Hardening-Carbon and Carbide-Carbon in, Determination of, (Jupitner and Jonstorf)	561
Manufacture of, (P) De Moya	616
Manufacture of, (P) Foote and others	806
Manufacture of, (P) Hadfield	444

Steel—*cont.*

Manufacture of, (P) Thompson, From La Société de l'Acier Gerard	749
Manufacture of Casts, (P) Giers	47
Manufacture of Polished Sheets of, (P) Gray and Gwynne	67
Melting, Permeability of Crucible for, (Arnold and Knowles)	749
Nickels, Metallurgical Properties of, (Guillaume)	674
Nickels, Physical Properties of, (P) Lake, From Schweitzer and Lammwitz	713
Prod. of, (P) Lake, From Schweitzer and Lammwitz	147
Production of Ferro-Silicon Fluxes for Manufacture of, (P) Tucker and Hughes	805
Properties of Molybdenum, (Von Lipin)	1047
Relation of Tensile Strength to Composition of	681
The Carbide in, (Mylius, Foerster, and Schoene)	549
Use of Phenol for Tempering, (Leval)	46
Steels, Estimation of Nickel in Nickels, (Spuller)	470
Sterilising Apparatus, (P) Bronhead, From Dierks and Mollmann	74
Apparatus, (P) Cassa	74
Apparatus, (P) Fournier	754
Apparatus, Steam, (P) Delapine	1032
Still or Tank for Corrosive Liquids, (P) Bray	661
Worm Pipes and their Supports, (P) Edwards, From Rohrmann	692
Stills, Conveying Heat to Contents of, (P) Martin and Stapley	719
Stone, Artificial, for Grinding or Abrading Purposes, (P) Schum and Lessing	804
Artificial, from Broken Glass	44
Artificial, Manufacture of, (P) Clay	145
Artificial, Manufacture of, (P) Grünhut	241
Artificial, Manufacture of, (P) Kleber	849
Artificial, Manufacture of, (P) Maxwell and Beer	142
Artificial, Manufacture of, (P) Neffen	574
Artificial, Manufacture of, (P) Owen	615
Artificial, Manufacture of, (P) Turner	241
Artificial, Preparation of, (P) McLean	750
Artificial, Production of, (P) Boulton, From Jungebluth	331
Artificial, to Resist Fused Alkalis Ac, (Hempel and Seziarski)	142
Hardening, (P) Jones	681
Objects, Ceramic, Manufacture of, by Devitrification of Glass, (P) Gatchey	339
Stones, Manufacture of Artificial, Electrically, (P) Couzon and Defalque	45
Stoneware, Manufacture of, (P) Winsor	442
Storage Batteries, See under Batteries	
Storax, Cinnamic Acid from, (Chassens)	952
Straws, Carbohydrates of the Cereal, (Cross, Bevan, and Smith)	691
Strontium Aluminate and Sulphate, Prod. of, (P) Leniakoff	240
Barium and Calcium, Separation of, (Rawson)	143
Chromate, Action of, on Mercuric Chloride, (Belugou)	509
Chromate, Action of, on Mercuric chloride, (Lambert and Belugou)	509
Sulphide, Phosphorescence of, (Monrelo)	642, 704
Sulphide, Preparing Highly Phosphorescent, (Monrelo)	642
Sulphide, Production of, (Monrelo)	1050
Sulphides, Stability of Phosphorescent, (Monrelo)	1050
Strophanthus Hispidus, Oil of the Seeds of, (Mjoe)	72
Seeds, Adulteration of, (Siedler)	1036
Sublimations, Apparatus for, (Paul)	699
Succinic Acid in Wine, Determination of, (Muller)	167
Suds, Treatment of Woolcombers'	694
Suede or Glove Kid, Tanning	152, 685
Sugar, Action of Sulphurous Anhydride on, (Grundmann)	59
Alleged Formation of Humul from, (Von Feilitzen and Tollens)	1028
Ammonia in Manufacture of Beetroot, (Jesser)	153
Analysis, Beetroot	152
And Glucose in Beetroot, Influence of Nitrogen on Properties of, (Uhlman)	60
Beets, Returns for 1895-96, German, (T.R.)	574
Beets, Occurrence of Raffinose in American, (Stone and Baird)	472
Boiling, (P) Shaw	251
Cane in the French West Indies, A New, (T.R.)	573
Cane Juice, Clarification of, (Beeson)	345
Cane, Levulose in Ripe, (Prinsen-Geerlings)	688
Canes, Sampling and Analysis of	687
Centrifugal Machines for Drying, (P) Abell	56
Conditions of Inversion of in Diffusion Juice, (Pellet)	623
Content of some Tropical Fruits, (Prinsen-Geerlings)	159
Crisis in German Production of, (T.R.)	574
Customs Duties on, in Foreign Countries, (T.R.)	572
Determination of Invert, (Lévy)	167
Diffusion Juice, Conditions for Obtaining Dense, (Mittelmann)	1027
Direct Estimation of, in the Beetroot, (Sachs)	69
Extracting, from its Solutions, (P) Wohl	56
Extraction of, from Molasses, (Eddy)	625
Extraction of, from Molasses, (P) Eddy	694
Extraction of, from Saccharine Liquors, (P) Feld	254
Factories, Indeterminate Losses in Cane, (Pellet)	925
Factories, Collated Methods of Analysis for, (Neumann, Feleman, and Herles)	69
Formation in Barley and Malt, (Grüss)	691
From Molasses, Extracting, by Baryta, (Lammert)	152
Group, New Synthesis in the, (Fenton)	268

Sugar—cont.	PAGE	Sulphur—cont.	PAGE
Hydrolysis of Cane, by Invertase, (Brown and Pickering).....	624	Dioxide, Starch Transformation by, (Berse).....	548
In Beetroots, Determination of, (Kaiser).....	364	Exportation of, from Italy, (T.R.).....	645
In Beetroots, Methods of Estimating, (Grafton).....	364	Extraction of, from Brimstone Earths, (White).....	42
In Chocolate and Foods, Determination of, (Pellet).....	474	Extraction of, in Sicily, (Aichiro).....	459
In Water, Law of Contraction in Solution of, (Wohl).....	451	In Coal-Gas, Apparatus for Estimation of, (Fischer).....	760
In Wine, Detection and Quant. Determination of, (Kalschek).....	475	In Copper, Estimation of, (Holland).....	164
Influence of Lead Salts on Estim. of Invert, (Bontzinger).....	49	In Iron and Steel, App. for Determination of, (Meade).....	934
Invert, Formation of, during Diffusion, (Pellet).....	1027	In Pig Iron, Determination of, (Blair).....	469
Juice and Liquor, Filtration of, (Bando).....	622, 622	In Pyrites, Determination of, (Glaser).....	262
Juice and Vapour in Vacuum App., Temp. of, (Glassem).....	152	Oils, Estimation of Free Sulphur in, (Morpurgo).....	166
Juice, True, Nature of Reducing Substances of, (Pellet).....	250	Oxides and Lead, Reactions between, (Jenkins and Smith).....	539
Juice, Carbonizing of Cane, (Geelers).....	451	Precipitation American, (Reed).....	931
Juice, Granulation of, (P) Grosse.....	327	Production in Sicily, (T.R.).....	271
Juice, Observations on Boiling of, (Curran).....	1028	Recovering, from Sulphur-tipped Hydrogen, (P) Brock and Hurter.....	556
Law, New French, (T.R.).....	572	Recovery of, from Hydrogen Sulphide, (Carulla).....	980
Liquors, Solubility of Barium Sulphate and Sulphate in, (Weissberg).....	254	Selenium in Commercial, (Reed).....	935
Liquors, Solubility of Sulphate of Lime in, (Weissberg).....	254	Sulphuretted Hydrogen, See under Hydrogen.	
Manufacture, Checking Losses in Diffusion, (Pellet).....	739	Sulphuric Acid, Action of Dilute, on Nitrates in Presence of Ether, (Tamm).....	767
Manufacture of, (P) Bauer.....	451	Acid, Action of Hydrogen on, (Berthelot).....	1051
Of Diffusion in Juice, Conditions of Inversion of, (Jesser).....	371	Acid, Action of, on Coal-Gas, (Fritzsche).....	1005
Production in France, (T.R.).....	252	Acid, Action of, on Levo-rotatory Turpentine, (Bourchardat and Lafont).....	931
Pr. T. and, (P) Janssen.....	762	Acid, Action of, on Mercury, (Berthelot).....	1051
Pr. T. Estimation of Lime in, (Pellet and Castels).....	688	Acid, Action of, on Oleic Acid, (Lewkowitsch).....	391
Process for Decolorizing and Purifying, (Oyent).....	689	Acid, Action of, on Petroleum, (Zaloziecki).....	994
Refinery at Lourenço Marques, Establishment of, (T.R.).....	771	Acid, Action of, on Wool-fat Alcohols, (von Cochenhausen).....	447
Refining and Purifying, (P) Ranson.....	816	Acid, Apparatus for Concentrating, (P) Dyson.....	413
Refining by Barium Peroxide, (Ranson).....	625	Acid, Classification of, in Portuguese East Africa, (T.R.).....	649
Refining: Methods of Defecation in Louisiana, (Thiele).....	451	Acid-making Apparatus, Joint for Pipes in, (P) Duggan.....	329
Samples, Filtration and Cupric-Reducing Power of Invert, (Brown, Morris and Muller).....	166	Acid, Manufacture of, (P) Garway.....	263
Samples, Clarification of, for Analysis, (Neumann).....	167	Acid, Manufacture, Reduction of Chamber Space in, (Hartmann).....	1015
Samples, Crystallization of, (Herzfeld).....	452	Acid, Method and App. for Evaporating, (P) Schwab.....	913
Samples, Inversion of, by Sulphurous Acid, (Stiepel).....	315	Acid, Purifying and Concentrating Spent, (P) Knoch and Co., and Coking.....	1049
Samples, Nitrate of Lead for Decolorizing, (Pellet).....	472	Acid, Refining Petroleum with Fuming, (Boleg).....	1069
Speed of Reduction of Ferric Alum by, (Long).....	1052	Acid Tank Wagons, Cleaning, (Norenberg).....	141
Sugar, Gum, &c., Class XVI., 35, 152, 250, 342, 451, 547, 657, 749, 816, 927, 1027.....	622	Acid, Volumetric Determination of Combined, (Marbouth and Moline).....	1941
Synthesis of Cane, (Marchlewski).....	622	Acids, Freezing Points of Dilute, (Hillmayr).....	535
Tax, Effects of New German, (T.R.).....	477	Sulphurous Acid, Inversion of Sugar Solutions by, (Stiepel).....	315
Waxes, Sediment, Unsuitability of, for Making Mortar.....	681	Acid, Obtainment of, (P) Hardingham, From Hunting-ton and Heberlein.....	683
Works, Treating the By-Products of, (P) Salts.....	57	Acid, Treating Sulphide Ores to Obtain, (P) Huntington and Heberlein.....	543
Years, Degree of Alkalinity of Raw, (Mittelstaedt).....	56	Anhydride, Action of, on Sugar, (Grundmann).....	56
Determination of Reducing, (Defren).....	264	Sumac, Adulteration of, (Eitner).....	1044
Calometric Estimation of, (Roulin).....	765	Adulteration of, in Italy, (T.R.).....	637
Used in Brewing, Estimation of, (Frey).....	312	Adulterations of, and their Detection, (Spica).....	639
Sugar-Treated Bromo-Cyanide Gold Extraction Process, Sulman and Teed.....	991	Trade of Italy, (T.R.).....	272
Sulphamide Benzoic Acid Alkyl Esters, Manufacture of, (P) Chemische Fabrik von Heyden.....	463	Sumatra Petroleum in, (T.R.).....	477
Sulphonic Acids, Products of Action of Tetramethyldiamido-diphenylmethanol on Para and Meta-, (Suares).....	608	Sumflower Seed, Proteids of the, (Osborne and Campbell).....	820
Sulphammonites of Silver, (Pouget).....	768	Superphosphate, Apparatus for Drying, (P) Johnson, From The Verein Chemischer Fabrik.....	54
Sulphate of Ammonium, See under Ammonium.		Superphosphates, Analysis of, (Coste).....	1165
Sulphates, Abnormal Fusibility of Mixture of Alkaline and other, (Le Châtelier).....	43	Estimation of Iron and Alumina in, (Von Gruber).....	104
Action of Hydrochloric Acid Gas on Alkali, (Colson).....	141	Manufacture and Storing of, (P) Mooney and Dickson.....	547

Tannin, Action of, on Alkaloids. (de Coninck).....	470	Thiel and Bertrand, Open-Hearth Process of, Combined. (Bertrand).....	542
Action of, on Quinoline Bases. (de Coninck).....	765	Thiobenzophenone, Preparation of Pure. (Gattermann and Schulze).....	134
And Gallic Acid, Action of, on Alkaloids. (de Coninck).....	639	Thiocyanates in Gas Liquors, Conversion of, into Alkali Ferrocyanides. (Dubosc).....	328
Estimation of. (Aweng).....	364	Thiocyanides from Spent Gas Purifying Materials. (Holling).....	37
Extracts, Behaviour of, to Hubl's Iodine Solution. (Boettlinger).....	640	Thio-orthobenzoic Acid, Preparation of. (P) Hauff.....	1035
Extracts, Manufacture of. (Fuchs and Schiff).....	161	Thiophene, Removal of, from Benzol. (Heusler).....	131
Hide Powder Determination of. (Yocum).....	419	Thiosulphate in Metal Developer, Effect of. (Hauff).....	559
Tanning Hides and Skins, and Prep. thereof. (P) Daniel.....	622	Thiosulphates, Removal of, from Photos. (P) Mercier.....	825
Apparatus for. (P) Du Bois.....	926	Thomas Process for Treating Iron, Improvement of. (P) Pszczolka.....	616
Apparatus for. (P) Levinstein.....	342	Thoria, Behaviour of, with Oxalic Acid and Ammonium Oxalate. (Glaser).....	498
Chromate Process of. (Jean).....	340	Estimation of. (Glaser).....	498
Continuous Method of. (P) Schmidt and Lindini.....	547	In Thorite, Estimation of. (Hantz and Weber).....	357
Extracts, Manuf. of. (P) Lake. From Lepetit and others.....	436	Thorite, Estimation of Thorium in. (Hantz and Weber).....	357
Leather, Glue, and Size. (Class XIV.).....	52, 122, 218, 310, 450, 516, 620, 686, 747, 816, 925, 1025	Thorium Nitrate, Crystallised. (Fulise).....	429
Mangrove Bark for. (Gurke).....	54	Oxide, Obtaining. (P) Buddens.....	824
Method of. (P) Levinstein.....	342	Salts, Duty on, in France. (T.R.).....	269
Process. (P) Clark. From Les Fils de F. P. Henrich.....	816	Sources of.....	120
Process. (P) Doley.....	816	Threads, Dyeing Vegetable. (P) Liebmann.....	911
Quebracho, Difficulties in. (Eitner).....	150	Production of Lustrous Effect on. (P) Liebmann.....	795
Tannin Reaction. (Aweng).....	364	Thyme Oil, Determination of Thymol in. (Kreimers).....	568
Tar Oil, Heavy, Miscible with Water. (Jézou).....	629	Thyroid Extract, Manuf. of. (P) Farb, vorm. Bayer and Co., Gland, Production of Active Constituents of. (P) Imray.....	103
Oils, Apparatus for Vaporising. (P) Fraipont.....	728	Tiles, Defective Flooring.....	650
Paving, Manufacture of. (P) Just.....	331	Efflorescence on. (Günther).....	738
Products. (Class III.).....	38, 139, 322, 431, 528, 606, 666, 722, 791, 904, 1008	Manufacture of. (P) Fludder and Innes.....	916
Tars, Production of Benzene and Toluene from. (P) Meikle.....	945	Manufacture of Artificial Stone. (P) Thomson.....	860
Tariff Changes and Customs Regulations.....	73, 263, 399, 572, 643, 706, 769, 836, 943	Tin, Analysis of. (Prost and Van De Casteele).....	827
Changes in the United States. (T.R.).....	370	And Antimony, Electrolytic Separation of. (Wallor).....	1013
Modifications of Belgium. (T.R.).....	769	Antimony Alloys, Micro-Chemical Exam. of. (Stead).....	506, 506
Modifications of Venezuela. (T.R.).....	769	Arsenic Alloys, Micro-Chemical Exam. of. (Stead).....	506, 506
Of Canada, New Customs. (T.R.).....	766	Arsenic and Antimony, Method of Separating. (Dancer).....	103
Of Japan. (T.R.).....	770	Arsenic and Antimony, Qualitative Separation of. (Ryerson).....	113
Tartar, Cream of, in Canada. (T.R.).....	771	In Bronze, Determination of. (Holland).....	763
Emetic or Antimony Fluoride Salts. (Ehrhardt).....	41	In Tin-Plate, Estimation of. (Mastbaum).....	709
Emetic or Antimony Fluoride Salts. (Ehrhardt).....	41	Ore, Treating Slaz from. (P) Bohne.....	919
Estim. Modif. of Goldenberg's Method for. (Zeechin).....	168	Ores, Treatment of. (P) Chaus.....	746
Tartaric Acid, Colour Reactions Yielded by. (Pinner).....	361	Oxide, Treatment of. (P) Von der Linde.....	742
Acid, Obtaining. (P) Schmitz and Toenges.....	799	Plate Varnish, Gold-coloured.....	815
Materials, Production of, in Italy. (T.R.).....	945	Recovery of, from Spent Tin Baths. (Vignon).....	43
Tartrates, Process for Obtaining. (P) Schmitz and Toenges.....	799	Scrap, Electric Treatment of.....	48
Tartrazine, Constitution of. (Anschutz).....	324	Tinctures, Export of, in Bond. (T.R.).....	843
Tasmania, Discovery of Zircons in. (T.R.).....	387	Export of Medicinal. (T.R.).....	918
Tax on Sugar in Germany, Effects of. (T.R.).....	477	Titanium and Tungsten, Separation of. (Defezqz).....	60
Tea, Analysis of. (Aclot).....	365	Cyanide Nitride in Blast-Furnace Slaz. (Frankel).....	942
Detection of a New Adulterant of. (Delait and Lomay).....	700	Oxide, Prod. of Fast Colours on Fibres by. (P) Barnes.....	238
Essential Oil of.....	556	Tobacco, Manufacture of. (P) Pscherhofer.....	559
Estimation of Caffeine in. (Hilger and Juckemaek).....	567	Treatment of. (P) Webers.....	821
Estimation of Caffeine in. (Keller).....	568	Tolu Balsam, Spurious. (Braithwaite).....	657
Estimation of Caffeine in. (Spencer).....	568	Toluene, Chlorine Derivatives of, Manufacture of. (P) La Société Chimique des Usines du Rhône.....	1039
Manufacture of Products from. (P) Davidson.....	457	Production of, from Oils and Tars. (P) Meikle.....	905
Relation between Caffeine in, and Quality of Chinese. (Graff).....	694	Sulphonic Acid, Ortho, Preparation of. (P) Hauff.....	1029
Technical Schools on the Continent: Report of Manchester Deputation.....	833	Toluenesulphonic Chloride, Prod. and Purif. of. (P) Majert.....	905
Telephone, Quantitative Analysis by means of the. (Erdmann).....	636	Tonkin, India-Rubber in. (T.R.).....	708
Telluride Gold Ores. (Pearce).....	541	Tortoise-shell, Substitute for. (P) Cadoret.....	449
Tellurium from Griffith Lode, Colorado. (Pearce).....	242	Towers, Construction of Glover. (Niedenfuhr).....	912
In Montana, Occurrence of. (Pearce).....	242	Construction of Glover and Gay-Lussac. (P) Jensen, From Lunge and Rohmann.....	537
Production at Schmitz. (Farky).....	116	Toxicodendrol, Investigation of. (Pfaff).....	1037
Temperature Determinations in Pottery Furnaces.....	143	Trade Report... 72, 170, 269, 369, 474, 572, 643, 704, 769, 835, 943, 1052	
Tennessee, Mount Pleasant Phosphates in. (T.R.).....	477	Transvaal, Chemical Industry in the. (T.R.).....	842
Terebenthene Monohydrochloride, Manufacture and Application of. (P) McIntosh.....	1033	English Cement in the. (T.R.).....	574
Test Papers, and Receptacles for same. (P) Brombeil. From The Chemische Fabrik and Dieterich.....	1040	Treasurer's Annual Statement.....	490
Testing, Unification of Methods of. (T.R.).....	375	Trees, Chemical Substances in the Trunks of. (Storer).....	1049
Tetra-iodo-Ethylene, Preparation of. (Biltz).....	757	Tricetone-Amine Series, Tropenes of the. (Harriss).....	822
Tetramethyldimethyldiphenylcarbinol, Products of Action of, on Para- and Meta-Sulphanilic Acids. (Snaiss).....	608	Triangle, Substitute for a Pipeclay. (Fairley).....	395
Tetranitro Cellulose, Manufacture of Solutions of. (P) Bronner and Schlumberger.....	355	Triphenyl-L-Gallic Acid, Prod. of. (P) Landshoff and Meyer.....	824
Tetranitrophenol and Diquinoyltriokime. (Nietzki and Blumenthal).....	252	Trichloropurine, Production of. (P) Boehringer.....	758
Tetraphenyl Methane. (Gomberg).....	942	Trimethylene, Decomposition of, by Heat. (Haber and Oechelhauser).....	528
Texas, Petroleum in.....	1009	Triphenyldioxazine Derivatives. (Auwers and Rohrig).....	607
Petroleum in. (T.R.).....	842	Triphenylmethane Colouring Matters, Prod. of Red. (P) Valle.....	457
Textile Plants, Treatment of, to Remove Fibre. (P) Bachelerie.....	1043	Triphenylmethane Series, Bases of the. (Weil).....	131
Textiles. (Class V.).....	41, 137, 234, 326, 437, 532, 609, 677, 736, 795, 907, 1012	Tropenes of the Triacetone-Amine Series. (Harriss).....	822
Bleaching Vegetable. (P) Gomess.....	1014	Tropoeoline, Production of. (Paul).....	730
Bleaching Vegetable. (P) Kent.....	439	Troughs for Glass-melting. (P) Thompson. From Muller.....	612
Dyeing and Finishing. (P) Jacob.....	911	Tubes, App. for Electro-Deposition of Metals on. (P) Cowper-Coles Galvanising Syndicate and Cowper-Coles.....	746
Soaps for.....	1023	Apparatus for Manufacture of, by Electrolytic Deposition. (P) Elmore. From Elmore.....	746
Toughening of. (P) Jelley.....	796	Tungsten and Antimony, Separation of. (Hallopeau).....	358
Treatment of. (P) Schneider.....	795	And Titanium, Separation of. (Defezqz).....	66

## INDEX OF NEW BOOKS.

	PAGE
Analyse der Fette und Wacharten. (Benedikt).....	570
Analyst's Laboratory Companion, The. (Johnson).....	942
Anleitung zu Analytisch-Chemischen Uebungsarbeiten auf Pharmaceutischem und Toxicologischem Gebiete. (Schäfer und Zenetti).....	571
Anleitung zur Chemisch-Technischen Analyse, &c. (Ulzer und Fraenkel).....	571
Anleitung zur Quantitativen Bestimmung der Organischen Atomgruppen. (Meyer).....	571
Chemiker-Kalendar, 1898. (Biedermann).....	942
Chemisch-Technisches Repertorium. (Jacobsen) ...	268, 571, 768, 835
Chemisch-Trockene Reinigung von Kleidungs-Stücken, &c. (L. Abel).....	1052
Chemistry of Dairying, The. (Snyder).....	268
Course of Practical Chemistry, A. (Pattison Muir).....	705
Die Chemische Technologie der Brennstoffe. (Fischer).....	571
Die Untersuchung der Schmiermittel und Verwandter Produkte der Fett- und Naphta-Industrie. (Holde).....	768
Einführung in das Studium der Alkaloids. (Guareschi).....	475
Elektrochemische Uebungsaufgaben für das Praktikum, &c. (Oettel).....	268
Elements of Electro-Chemistry, treated experimentally. (Lapke. Translated by Pattison Muir).....	369
Engineering Chemistry. (Stillman).....	368
Entwicklung, Bau und Betrieb der Elektrischen Ofen zur Gewinnung von Metallen, Carbiden, und Anderen Metallurgisch-wichtigen Produkten. (Borchers).....	369
Fabbricazione dell' Acido Solfonico, dell' Acido Nitrico, del Solfato Sodico, dell' Acido Muratico. (Vender).....	768
Four Électrique, Le. (Moissan).....	369

	PAGE
Handy Book for Brewers. (Wright).....	268
Jahresbericht über die Leistungen der Chemischen Technologie. (Fischer).....	571
Leghe Metalliche ed Amalgame Alluminio, Nichelio, Metalli Preziosi e Imitazioni Bronzo, Ottone, Monete e Medaglie, Saldature. (Gherzi).....	768
Les Nouveautés Chimiques pour 1887. (Baillière et Fils).....	267
Lubricating Oils, Fats, and Greases. (Hurst).....	72
Manuale del Chimico e dell' Industriale. (Gabba).....	768
Manuel d'Analyse Chimique. (Fleurent).....	1052
North American Conifers, Some. (Bastin and Trimble).....	942
Notes on Assaying. (Ricketts and Miller).....	369
Organic Chemical Manipulation. (Hewitt).....	705
Organic Chemistry for the Laboratory. (Noyes).....	855
Precis d'Analyse Chimique. (Fink).....	267
Principles and Practice of Agricultural Analysis. Vol. III. Agricultural Products. (Wiley).....	369
Principles and Practice of Brewing, The. (Sykes).....	942
Printing of Textile Fabrics, The. (Rothwell).....	369
Prospector's Handbook, The. (Anderson).....	705
Recueil de Procédés de Dosage. (Arth).....	267
Short Studies in Physical Science, Mineralogy, Chemistry, and Physics. (Cornish).....	267
Some Unrecognised Laws of Nature. (Singer and Berens)...	475
Subject Matter Index of Technical and Scientific Periodicals..	1052
Tabellen für Gasanalysen, &c. (Lunge).....	268
Tables for Quantitative Estimation of the Sugars. (Wein. Translated, with additions, by W. Frew).....	72
Theorie und Praxis der Analytischen Elektrolyse der Metalle. (Neumann).....	268
Traité Élémentaire de Chimie. (Haller and Muller).....	267

# LIST OF ERRATA.

Page.	Column.	Line.	Description.
1897.			
58	2	6	From bottom: for "tested" read "tasted."
169	2	21	From top: for "rays" read "rays."
409	2	23	From top: for "rays" read "rays."
167	1	1	For "Bordes" read "Bordas."
510	2	7	From top: Explanation of Fig 1: for "and" read "α" alpha.
522	2	10	Second Diss. etc 1 form ill lacks below, " $\text{CH}_2$ ."
523	2	1	From top: for "Prima seconds" read "Good seconds."
523	2	13	From top: for "1 sq. cm." read "1 sq. decim."
598	2	..	Figs. I. and II. should be reversed, or be numbered II. and I.
574	1	33	From top: add the reference, "This Journal, 1896, 597."

# THE JOURNAL OF THE Society of Chemical Industry:

## A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 1.—Vol. XVI.]

JANUARY 30, 1897.

Non-Members 30/- per annum; Members  
21/- per Set of extra or back numbers;  
Single Copies (Members only) 2/6.

### The Society of Chemical Industry.

#### Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
Sir Frederick A. Abel, Bart., K.C.B., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
T. E. Thorpe, LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.

### COUNCIL FOR YEAR ENDING JULY, 1897.

**President:** Dr. Edward Schunck, F.R.S.

#### Vice-Presidents:

Chas. Dreyfus.	E. C. C. Stanford.
Dr. A. Dupré, F.R.S.	G. N. Stoker.
Prof. A. K. Huntington.	Dr. T. E. Thorpe, F.R.S.
Boverton Redwood.	Prof. W. A. Tilden, F.R.S.
Sir H. E. Roscoe, F.R.S.	Thomas Tyrer.
A. Gordon Salomon.	

#### Ordinary Members of Council:

George Beilby.	C. C. Hutchinson.
R. Forbes Carpenter.	Ivan Levisstein.
R. Le Neve Foster.	J. S. McArthur.
Oscar Guttman.	B. E. R. Newlands.
Douglas Herman.	Sir Robert Pullar.
David Howard.	Wm. Thorp, B.Sc.

With the Chairmen and Secretaries of Sections.

#### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

#### Honorary Foreign Secretary:

Dr. Ludwig Mond, F.R.S.

#### General Secretary: Charles G. Cresswell.

Offices: Palace Chambers, 9, Bridge Street, Westminster, S.W.

### THE JOURNAL.

#### Publication Committee:

The President.

A. H. Allen.	C. Clarke Hutchinson.
G. H. Bailey, D.Sc., Ph.D.	Wm. Kellner, Ph.D.
Joseph Bernays, M.I.C.E.	J. Lewkowitsch, Ph.D.
H. Brunner.	A. R. Ling.
A. C. Claudet.	Ludwig Mond, F.R.S.
E. Rider Cook.	B. E. R. Newlands.
Chas. Dreyfus.	John Pattinson.
Sir John Evans, K.C.B., F.R.S.	W. H. Perkin, Ph.D., F.R.S.
G. G. Henderson, D.Sc.	H. R. Procter.
John Heron.	Boverton Redwood.
D. B. Hewitt, M.D.	Walter F. Reid.
David Howard.	John Spiller.
Prof. J. J. Hummel.	William Thorp.
Prof. A. K. Huntington.	Thomas Tyrer.
F. Hurter, Ph.D.	Lewis T. Wright.

#### Editor:

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

Assisted by the following Staff of Abstractors:

### NOTICES.

#### COLLECTIVE INDEX.

A collective index, embracing the whole Journal from the Proceedings of the First Annual General Meeting, 1881, to the close of 1895, is now in preparation, and will be ready shortly. It will contain both a subject-matter and authors' names portion, and will be a volume of about 500 pages, uniform in size with the Journal.

The prices will be as follows:—

To Members (see Rules 25 and 27) and Past Members (see Rule 30); Libraries, Corporations, and Exchanges on the Society's List	Each copy 10s.
To Subscribers .....	„ 12s. 6d.
To others.....	„ 15s.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

#### NEW YORK SECTION.

##### *Change of Address.*

The official address of the Hon. Local Secretary, Dr. H. Schweitzer, is changed from 159, Front Street, to 77, William Street, New York, U.S.A.

#### LIST OF MEMBERS ELECTED 22nd JANUARY 1897.

- Adams, Thos. H., Chemical Laboratory, Loco. Dept., Midland Railway, Derby, Analyst.  
 Cohn, Alf. J., 2, East 107th Street, New York City, U.S.A., Chemist.  
 Gaster, Leon, 37, Maida Vale, W., Electrical Engineer.  
 Gundlich, Dr. Chas., 451, East 84th Street, New York City, U.S.A., Chemist.  
 Hicks, Edwin F., 203, West 81st Street, New York City, U.S.A., Analytical Chemist.  
 Hotson, Arthur E., 1 and 3, Union Square, New York City, U.S.A., Chemist.  
 Hyams, Geoffrey M., 312, Sears Building, Boston, Mass., U.S.A., Mines Manager.  
 Leathart, Thos. H., Bracken Dene, Gateshead-on-Tyne, Lead Manufacturer.  
 Lindsay, Robt., Avenue Cottage, Alexandria, N.B., Chemist.  
 McCrae, Dr. Jno., jun., Mason College, Birmingham, Student of Chemistry.  
 Myers, Prof. H. C., Washington State University, Seattle, Wash., U.S.A., Professor of Chemistry.  
 Osborne, Thos. B., P.O. Box 485, New Haven, Conn., U.S.A., Chemist.  
 Smith, Geo. J., Bickford, Smith, and Co., Tuckingmill, Cornwall, Fuse Manufacturer.  
 Steinhart, Dr. Oscar J., 4, Palace Street Mansions, Buckingham Gate, S.W., Manufacturing Chemist.  
 Ullman, Jas. A., 2 o Jaencke-Ullman Co., 536, Pearl Street, New York, U.S.A., Chemist (Printing Ink Works).  
 Vogel, Julius S. F., Hillersdon, East Molesey, Surrey, Engineer.  
 Wells, Dr. Jas. S., Chester, P.O. Box 95, Hackensack, N.J., U.S.A., Instructor in Analytical Chemistry.  
 Williams, W. Lloyd, Phoenix Mills, Dartford, Kent, Chemist and Manager.

#### CHANGES OF ADDRESS.

- Angell, Jnn., 1/o Fallowfield; 6, Beaconsfield, Derby Road, Withington, Manchester.  
 Barnes, E. A., 1 o London; Dynamite Works, Zuurfontein, S.A.R.  
 Boake, A., 1 o Highgate; Warton Road, Stratford, E.  
 Bowman, Prof. Walker, 1 o Athens; c o Louisville Spirit-Cured Tobacco Co., Louisville, Ky., U.S.A.  
 Bowrey, J. J., 1 o South Hackney; (subs.) 28, Belmont Road, Ilford, Essex.  
 Brookman, F. W., 1 o Entwisle Road; 176, Ramsay Street, Rochdale.  
 Cameron, Jas., 1 o Bridge Street; 11, Bolton Road, Port Sunlight, Birkenhead.  
 Carmichael, Dr. H., 1 o Post Office Square; 12, Pearl Street, Boston, Mass., U.S.A.  
 Chadwick, W. M., 1 o Natroon; 24, West 3rd Street, Bayonne, N.J., U.S.A.  
 Cashman, Allerton S., 1 o St. Louis; Prescott Hall, Cambridge, Mass., U.S.A.  
 Davies, Ll. J.; Journals to Bute Chambers, Bute Road, Cardiff.

- Davis, H. J.; all communications to 65, Wall Street, New York, U.S.A.  
 Dawson, Jas.; Journals to Eglington Dyewood Mills, Alloa, N.B.  
 Dewar, Jno. A., 1 o Melrose House; Baleraig, Scone, N.B.  
 Dreaper, W. P., 1 o Great Yarmouth; Clifton Villa, Coggeshall Road, Braintree, Essex.

#### SESSION 1896-97.

Feb. 1st.—Mr. E. Andreoli. "Ozone: its Production and Industrial Applications."

Feb. 15th.—Mr. W. J. Dibdin. "The Character of the London Water Supply." Adjourned Discussion.

Meeting held on Monday, January 4th, 1897.

DR. R. MESSEL IN THE CHAIR.

## THE SMELTING AND REFINING OF CYANIDE BULLION.

BY ARTHUR CALDECOTT, B.A. (C.G.H. UNIV.).

THE precipitate produced in the MacArthur-Forrest cyanide process by the passage of gold-bearing cyanide solutions through filiform zinc varies in character according to the nature of the ore and the strength of the solutions employed.

It is collected by screening in water the contents of the extractors through sieves, of which the meshes may be  $\frac{1}{2}$  inch or less, and then draining off the liquid through a filter cloth. To hasten filtering and drying a filter press may be employed. By this means the bulk of the fine material, with its gold contents, is separated from the coarser portion, which is returned to the extractors. A somewhat coarse sieve is advisable, as the finer particles of zinc, which would otherwise tend to accumulate and clog in the extractors, are thereby removed.

The components of the precipitated gold slimes, as they are called, of which special account must be taken in the conversion into bullion, are shreds of zinc and zinc cyanide, copper from the ore, iron, arsenic, lead, and other metallic impurities of the zinc which are insoluble in cyanide solutions, zinc ferrocyanide, of which the iron is liable to be reduced to the metallic state, zinc hydrate, ferric hydrate, calcic carbonate, sand, and other oxy-compounds which are readily fluxed, and mercury derived from the amalgamated copper plates. From the nature of these constituents they may obviously be divided into those metallic oxy-compounds which readily combine with the fluxes subsequently used, and the metals and cyanide compounds which tend to act as reducers and render the bullion base. These latter it is necessary to oxidize preliminary to smelting.

At one time it was common practice on the Witwatersrand to mix the dried slimes with fluxes and smelt at once, but this plan was found to be tedious, to produce very base bullion, and to leave a large amount of gold in the slag; owing to the ammoniacal gases and steam evolved on heating, the crucible was liable to boil over and violently eject the contents, causing loss of gold. By subjecting the slimes to a preliminary roasting on a tray, with free access of air, the volatile compounds were expelled and the base metals oxidized to a great extent. This preliminary roasting, however, of slimes alone, or of slimes mixed with 1 to 3 per cent. of nitre, usually takes a considerable time, as a red heat must be attained with each lot, and there is an appreciable loss of fine gold, which is carried off mechanically in the dust rising when the slimes are handled or stirred during the operation.

To expedite and improve this preliminary roasting the following plan was adopted, and found to give such good results that I have since used it to a large extent. 20 lb. dried slimes, containing 7 per cent. fine gold, were roasted and subsequently smelted in a No. 70 crucible; one pouring only was made, and yielded, besides the bullion, 34 lb. slag, containing 36 oz. fine gold to the 2,000 lb. ton, or 12 per cent. Slag as usually produced in the smelting of gold slimes contains 100 oz. to 200 oz. to the ton, and is crushed and panned, whereby a considerable amount of gold is recovered, but there is also a certain loss of fine float gold; the tailings are then sold to smelters, or put through the mill. This last is a bad plan, as however carefully amalgamation and subsequent concentration and cyaniding be conducted, sufficient gold still remains in the slags to render them three or four times as rich as average concentrates. If, however, the gold contents of slag as produced be reduced to  $\frac{1}{2}$  per cent. they can be disposed of to smelters at once, and all losses during crushing, &c. avoided.

The 20 lb. of slimes above referred to were dried until dust just began to be apparent by rising on stirring. They were then thoroughly mixed with 30 per cent. (6 lb.) of their weight of fine dry quartzose sand and 20 per cent. (4 lb.) of finely-crushed nitre, and spread in a layer  $\frac{3}{4}$ -inch thick on a large iron tray (6 ft. by 3 ft.) of  $\frac{1}{2}$ -inch wrought iron, below which a small fire was kindled so as to raise it somewhat above 100° C. A live coal and pinch or two of nitre were then applied to the centre of the layer of slimes mixture, and quiet but intense combustion began, which gradually and regularly spread at the rate of about 6 in. per minute over the whole mass. Dense fumes were given off, and when combustion was complete all volatile materials were expelled, and a red-brown non-dusty product in brittle cakes remained. Three parts of dried slimes yielded 4 parts of this material. When cooled it was mixed with 40 per cent. (11 lb.) of its weight of anhydrous borax and 10 per cent. (2  $\frac{3}{4}$  lb.) of dry sodic carbonate, and smelted in a crucible. Fusion took place rapidly without violent

ebullition, and the slag, as stated, was comparatively free from gold. According to the composition of the slimes the above method of roasting, and the proportion of the fluxes may be varied as experience shows. Some slimes may require no heat at all, but combustion once started in the cold will continue, whilst others may require a very slight damping to prevent its being too rapid. The effect produced by the nitre is oxidation of portion of the carbonaceous matter and base metals, and a partial combination with the sand to form a fusible silicate. This serves to cement the particles of the material together and obviates dust. A portion of the zinc is volatilised along with the mercury and carbon dioxide, cyanogen, ammonia, steam, and other gases are evolved. Care should always be taken to use somewhat less nitre than is required to oxidise all the base metals, as, otherwise, during the subsequent fusion, the pots may be corroded and the gold pass into the slag as an alkaline aurate. The sand serves to moderate the combustion during roasting, and by forming a fusible silicate with the potassic hydrate produced by the reduction of the nitre, acts as a flux and protects the crucibles against corrosion by the basic oxides. A thick slag indicates insufficient flux or improper proportions, a corrosive slag requires more sand or borax, or both. Above the roasting tray should be a hood of sufficient size to catch all dust and fume, which is conducted by as direct a flue as possible to a large dust chamber, where the greater portion of the solid constituents are deposited.

In smelting it is advisable to add fresh flux slimes to the crucibles before the surface of their contents is quite fused to lessen possibilities of ebullition. When in perfect fusion and a few minutes before pouring, the contents of the crucibles should be well stirred to cause any globules of metal at the bottom to coalesce. The conical moulds used should be flat, not rounded, at the bottom of the inside, and should be greased and smoked and well warmed, otherwise, on pouring, the bulk of the metal is at once chilled, and solidifies, and the last molten drops are unable to unite with it, but remain as a layer of shot above the main piece. Should any of these globules be found, that portion of the slag containing them should be carefully separated from the rest and added to the next charge. Before pouring, the bulk of the slag may be removed by means of a shallow dipper, so that when poured there will be less depth of slag in the mould to entangle shots of metal. The same end may be attained by using a small conical mould above a tray into which the bulk of the slag overflows. By using dry sodic carbonate and dried or fused borax, which need not be very finely crushed, in place of sodic bicarbonate and hydrated borax usually employed, a great saving of time, labour, and fuel is effected, there being no combined water to drive off during smelting, and the danger of ebullition in the crucibles is reduced to a minimum. By this method a No. 70 plumbago crucible can be used for 10 or 12 pourings equivalent to smelting 2 cwt. of slimes, or a "life" of 36 hours in the furnace. Even then it shows more wear and tear on the outside than corrosion on the inside. In proportioning the fluxes for any particular case the object should be to produce a neutral fluid slag, so that the pots are not corroded, and the gold is not retained. The cost of a little more flux, or the production of somewhat more slag, is a small matter, so long as the greatest possible percentage of gold in the slimes is immediately converted into bullion.

SECTION OF CONICAL SLIMES SHOVEL.

Above is a sketch of a conical slimes shovel of thin sheet iron for charging the crucibles. It is filled through the opening near the larger end, and the handle being at an angle, permits of the contents being readily delivered into the crucible without spilling or allowing dust to be carried

off by the draught of the furnace. In making the shovel, the joining of the two edges of sheet metal should be on the upper side where the opening is. Box furnaces, lined with fire-brick, 22 ins. deep and 20 ins. square, and built with openings level with the floor, are of a suitable size for a No. 70 crucible, and nearly  $1\frac{1}{2}$  cwt. of slimes should be smelted in each per 24 hours. Altogether the drying, roasting, and smelting of even a large works should not occupy more than a couple of days. Long-handled basket tongs should be used, and made to fit the crucible. They are hoisted by a thin wire rope passing through a pulley-block on an overhead traveller, and terminating in a hooked rod which is attached to the pivot eye-bolt, by which the two halves of the toogs are joined. Possibly a small quick-action Weston pulley might be used with advantage. The moulds can be made after the type of the wheeled slag-pots used in cupelling silver-lead bullion, or else fitted with trunnions resting on supports, rising above a removable iron tray, on a frame provided with wheels and a handle. By this means, when the crucible is poured, the mould and its fused contents can be wheeled away from the furnace to cool. Any overflow from the mould during pouring is caught in the tray, and when the contents of the mould are turned out they also fall on the tray, which can then be removed.

A species of small reverberating furnace is sometimes also used successfully for smelting with coal; the crucibles come in contact with the flame only, and not with the solid fuel. To remove the greatest possible percentage of gold from the slimes, litharge and a reducer are used at a large rand company; of course this involves subsequent cupellation of the lead bullion. It is probable that in time this method will be very generally adopted where ready facilities for cupellation exist, as very little gold indeed is left in the slag. In companies in outlying districts, however, direct smelting of the slimes in bullion is likely to be practised for some time to come. Refining of gold slimes preliminary to smelting is occasionally done by means of dilute sulphuric acid in wooden tubs. This dissolves the zinc, &c., but removal of the solution of soluble sulphates by filtering and washing or by decantation is a very tedious process unless vessels considerably larger than the usual half-hogheads be employed. If not thoroughly washed out some of the sulphate is liable to be reduced in the crucible to a sulphide, with formation of a matte. This acid refining is perhaps advisable when so much mercury is deposited in the zinc boxes as to form an amalgam, and it is desired to purify this for retorting to recover the mercury and avoid danger of salivation, were the slimes roasted in the ordinary way. Mr. A. F. Crosse, of the Standard Bank, Johannesburg, informs me that he has successfully experimented with a solution of caustic soda for the removal of the bulk of the impurities in gold slimes by boiling, preliminary to smelting.

Should it be desired to further refine the bullion as above produced, or indeed any base bullion, before casting into bars, nitre may be used to effect this. It is commonly believed that the use of nitre for this purpose in plumbago crucibles is hardly permissible, on account of the corrosion of the pots, with the consequent possibility of the contents finding their way between the fire-bars into the ash-pit. As nitre refining is commonly performed, this hesitancy is justified, but if the following precautions be observed, large quantities of base metal can be readily oxidised and caused to pass into the slag with only slight corrosion of the crucibles. The chief point to be observed is that the nitre must be brought into immediate contact with the molten bullion, so that it does not expend its oxidising power on the plumbago of the crucibles. To effect this, a somewhat large crucible is used, so as to expose as large a surface of bullion as possible. The metal is melted without flux, and when molten, a couple of ounces of nitre are thrown in and immediately pressed gently down and kept in absolute contact with the surface of the molten metal. This is done by means of a plumbago stirrer, fastened to a long, thin bent iron rod. The stirrer is made from an old crucible by sawing a vertical piece out of the side attached to a portion of the bottom, about  $2\frac{1}{2}$  in. in diameter, which is hence at right angles to the iron rod. Dense fumes of zinc

oxide, &c. are evolved, and when the action ceases the process is repeated until a thick crust of scorina-like oxide forms on the surface. Some flux, consisting of a mixture of 3 parts of dry borax, 1 part of dry sodic carbonate, and 1 part of fine dry sand is added, and when fused the slag is either removed in the usual way, as detailed in the second volume of Aaron's Assaying, or else the pot is poured and the slag detached from the metal, which is replaced in the crucible for the process to continue till it is sufficiently refined. If a borax flux alone be used, there is sometimes considerable difficulty in detaching the layer of slag from the bar after pouring. If the nitre be added to the crucible along with the other fluxes, the greater portion of it never comes in contact with the metal at all, but attacks the crucible and causes violent boiling over of its contents. When, after the final pouring, the slag is solidified, the bar is turned out of the mould and tapped with a hammer to remove the bulk of the slag; the still hot bar is then placed in cold water to detach any slag still adhering.

Boiling of the bars for half an hour in dilute nitric acid, in a heavily enamelled iron dish with handles, considerably improves their appearances, but samples for determining fineness of the bullion should be taken beforehand.

For weighing and mixing slimes, a zinc covered table with raised edges and a row of flux bins at the back is very convenient. Ordinary oval galvanised iron baths with handles are also very useful in handling slimes and slags.

It need hardly be said that the most scrupulous care is required, especially in the earlier stages, in dealing with a material so rich and so easily dissipated as gold slimes. It is probable that the losses which occur and are only partially recovered as "sweeps" from the dust of the floor, which should be cemented, from the flues and fame chamber, from the ash of furnaces, &c. are considerably greater in many instances than are suspected.

#### DISCUSSION.

Prof. W. ROBERTS-AUSTEN said that from the assayer's point of view the question of the removal of zinc was of considerable importance. Much of the bullion coming from South Africa, where the cyanide process was largely used, was contaminated with zinc, owing probably to the want of some such process as the author had brought before them. In a triple alloy, in which the bulk was gold, a small proportion of zinc would have a remarkable effect on the relative distribution of the precious and base metal in the mass, which would assay far more accurately if zinc were not present. In fact, with zinc present, it was impossible to get a trustworthy assay, and any process that eliminated zinc and lead from the gold would be of value.

Mr. ARTHUR C. CLAUDET remarked that it would have been useful to know the fineness of the bullion after the treatment of the gold slimes, as also the amount of zinc and lead contained in the bullion. With regard to the effect of the presence of zinc in the bullion, he endorsed Prof. Roberts-Austen's remarks; but, in his opinion, it was not zinc only that affected the assay, but the presence of lead exerted a very considerable effect. Most of the mines using the cyanide process used a cheap zinc contaminated with lead, sometimes to the extent of 2.5 to 3 per cent. and more, and the whole of this was necessarily left in the mud with any zinc not removed. An analysis he made three or four years ago of a bar of bullion gave the following results:—

	Per Cent.
Gold .....	61.30
Silver .....	6.73
Lead .....	11.86
Copper .....	0.97
Zinc .....	11.93

In a bar of this composition it was difficult and generally quite impossible to get assays to agree by cutting pieces off the bar. Still it was not impossible to get reliable assays from cyanide bars, if the bar was properly melted and a "dip" properly taken from the molten metal in the crucible. The correct way was to use a small ladle and

take out enough metal, but so little that it would set immediately, thus preventing excessive segregation of the metals present. Then the pot should be stirred and another dip taken. Such a course gave accurate results if the bar were not very low—say down to 200 or 150. But with a fineness of 500 the dips would not differ more than a half to one millième. The main points to be observed were, first to separate mechanically as well as possible from the slimes the larger pieces of zinc, then treat the slimes with sulphuric acid, as at the Treasury mine in the Transvaal. Having done that, the gold remaining would yield a tolerably pure bullion. The fact still remained, in the zinc boxes pure zinc only should be used, because it was much better to keep impurities out than to have to eliminate them afterwards. He had already gone very fully into this question in a discussion on a paper, in the transactions of the Institute of Mining and Metallurgy, Vol. IV., entitled "Notes on the Treatment of Zinc Box Precipitate," by Robert Gilman Brown, read on May 20th, 1896. The importance of obtaining gold bullion free from lead and zinc, or nearly so, was gone into very carefully in his contribution to this discussion.

Dr. A. F. FURBER agreed with the previous speakers. By simply roasting the slimes one could get gold 990 fine, and if this process would not do better than that, there was no advantage in using it. He understood from a paper read by Mr. Matthey, lately, that if the amount of silver present in cyanide bullion was less than 30 per cent., it was impossible to get out the gold, because the precious metal concentrated in the middle of the bar.

Prof. ROBERTS-AUSTEN quite agreed with Mr. Claudet's remarks. In the particular case which he had cited, however, there was very little lead present, or he would have alluded to it.

The CHAIRMAN regretted the absence of the author, who was in South Africa. It was possible that some few points in the paper, which had been in the Society's possession some time, might have appeared in print elsewhere; but the delay was unavoidable, and the importance of the gold industry in South Africa fully warranted the bringing forward of the subject now. It was probable, however, that some one of the electrical processes would eventually solve the problem.

#### A RECORDING PYROMETER FOR INDUSTRIAL USE.

BY PROF. ROBERTS-AUSTEN, C.B., F.R.S.

THE communication which I have to offer the Society is hardly worthy of being called a paper; but as it may possibly prove to be useful to the members, I have much pleasure in laying it before them. There are practically only two methods which can be readily used in accurate pyrometric work. One of these is the well-known resistance pyrometer devised by Sir William Siemens, or the modification of it devised by Callendar. With this appliance three chemists are at present conducting some most interesting work at Cambridge. Mr. Griffiths, who has attained a degree of accuracy which is simply marvellous, and Messrs. Haycock and Neville, whose work has already been the subject of several communications submitted to another society which meets in this room. I need say nothing about the resistance pyrometer, because, admirable as it is, it is somewhat costly, and need not be employed for work that does not require minute accuracy—let us say, than a tenth of a degree at a thousand degrees—which may be justly claimed for it. The other accurate pyrometric method involves the use of a thermo-junction. The use of the thermo-junction pyrometer, however, dates from 1826, when the elder Becquerel devised and employed a number of thermo-junctions, finally adopting one of platinum and palladium. Joule, in 1859, showed that thermo-junctions might be used for registering the temperature of bars of iron submitted to longitudinal stress. But we owe the extended use of the thermo-junction to H. Le Chatelier, who, by his work from 1885 to the present time, has shown with what extreme accuracy its use may be attended, and who has, in fact, made Becquerel's instrument a very accurate one. Le Chatelier used originally platinum alloyed with 10 per

cent. of iridium, but abandoned that because he found a critical point in the iridium-platinum alloy; and he then employed a junction of platinum wire twisted with another platinum wire alloyed with 10 per cent. of rhodium. In 1873, when so much was thought of the iridium-platinum alloy for metrical standards, Prof. Tate employed a platinum-iridium alloy, and produced his well-known "first approximation to a thermo-electric diagram." That fact has been somewhat overlooked, and I mention it because, for actual industrial working, I have found it well to revert to this platinum-iridium alloy first used by Prof. Tate. Nothing is simpler than its use: it is only necessary to take a thin wire of platinum and twist it with another similar wire alloyed with a small amount of iridium, which is usually 10 per cent. It may be mentioned that a series of alloys are now being produced by Col. Matthies which are very rich in iridium, and it is confidently hoped that their use will enable temperatures to be measured which are higher than the melting point of platinum, to which we are now limited. All that is necessary is to take these wires, plunge their twisted junction into the metal or receptacle the temperature of which is to be ascertained, and the measurement may be effected, provided the free ends of the wires are connected with a galvanometer. The next thing is to calibrate the thermo-junction, and that is done by employing certain known melting points which have already been fixed by the aid of the air thermometer, to which all final references must be made. There is a consensus of opinion surrounding many of these melting points, and we may confidently accept them: the boiling point of water,  $100^{\circ}$ ; the melting point of lead,  $326^{\circ}$ ; the melting point of aluminium,  $650^{\circ}$ ; and, according to the recent determinations of Haycock and Neville and many other observers, the melting point of gold,  $1,062^{\circ}$ . There is also the melting point of palladium,  $1,500^{\circ}$ , and of platinum,  $1,775^{\circ}$ ; and, as I have said, Col. Matthies will, I hope, soon communicate to the Royal Society the results of some experiments with alloys of iridium and platinum, which will enable us to measure higher melting points still, at no very distant date. Copper may replace gold with advantage, because it can readily be obtained pure, and its melting point,  $1,082^{\circ}$ , is sufficiently accurate for practical purposes. The method of calibration is shown in the diagram, only in the case of gold it is always necessary to keep the thermo-junction from direct contact with the metal. Take a small crucible in which gold or copper is melted and allowed to solidify; if the two loose ends of the thermo-junction are connected with a galvanometer, and the junction, suitably protected, is plunged in the metal, the spot of light will traverse the screen, and as the metal freezes the spot will remain fixed till the whole of the metal is solid; that will give the freezing point of gold or of copper, as the case may be, and in that way any particular thermo-junction intended for use may be calibrated. The great advantage of using this instrument for industrial purposes consists in the fact that the spot of light from the galvanometer traversing photographic paper, is able to make a record, and that is done by the aid of a special appliance which I have devised for the purpose, and will now describe.

It consists of a box or camera, which is drawn as if it were transparent. The galvanometer G may be connected with each of the six thermo-junctions (J to J<sup>6</sup>) in turn. Each of these thermo-junctions is placed, suitably protected, in a furnace, the arrangement merely indicating the methods of making the connections of the six thermo-junctions with the galvanometer by means of the switch B. The handle of this enables either of the thermo-junctions to be connected with the galvanometer. The light from the gas flame L falls on to a mirror, A, and passes from it to the movable galvanometer mirror M, and is reflected from it through a fine horizontal slit to the drum D. This drum contains the clockwork which causes it to revolve once in 12 hours. Light from the mirror A also falls on to a fixed mirror, E, placed below the movable mirror of the galvanometer, and this enables a datum line to be traced on the sensitised photographic paper by which the drum is covered. The temperature to which any given thermo-junction is raised will be indicated by the position of the line which is traced on the paper by the spot of light falling from the mirror M.

The number of the particular furnace under examination is indicated as follows. The switch B is connected by a cord C with a strip of metal P, and this strip, which is

Fig 1.

supported by a spring S, bears a number of fine horizontal slits. If, for instance, No. 3 furnace is under examination, light from the lamp L will fall through a fine horizontal slit in the wall of the box containing the drum, and through three slits in the vertical strip P. A triple continuous datum line will be photographed on the drum as long as connection is maintained with No. 3 furnace. If No. 2 furnace is being tested, the datum line will be double, while if the furnace is No. 1, the line will be single.

A slide, H, may be screwed down so as to exclude light from the portion of the camera which contains the drum. This portion may then be removed to the dark room, where the record as traced on the sensitised paper is developed.

For industrial purposes you have a slight modification, and that is, that instead of a flat glass plate it is convenient to use a drum actuated by clockwork, around which a piece of bromide paper is placed. The drum revolves at a definite pace, and the deviations of the spot of light mark the angular deflection of the mirror and consequently variations in the temperature of the receptacle or of the metal or alloy in which the thermo-junction is placed, the result being that you have little or no difficulty in obtaining an accurate record of what has happened in the immediate vicinity of the thermo-junction. Take a specific case. The chief industrial use of the appliance, so far, has been in connection with the measurement of the temperature of the air supplied to blast furnaces.

The upper curve in Fig. 2 represents a record for  $23\frac{1}{2}$  hours of the temperature of the hot-blast supplied to a furnace by a series of stoves, numbered respectively Nos. 1, 2, 3. It is a typical record, and, as it represents an excellent sample of careful and successful gas-firing, it may be well to describe it in some detail.

It will be seen that the record begins near the top right-hand corner, and shows that the temperature of the blast contributed by No. 2 stove (at 10 a.m. on the 14th of February) had an initial temperature of  $1,160^{\circ}$  F. At the

end of an hour the temperature of the blast had fallen to 955° F., and the gas-man considered that the time had arrived for effecting the connection with a fresh stove, No. 3. As will be seen from the record, this stove contributed blast at an initial temperature of nearly 1,230° F., and

the temperature fell in the course of 1 hour and 50 minutes to 1,020° F., when the blast from No. 4 stove was introduced into the horseshoe main. Inspection of the curve will show the successive variations of temperature. The record, viewed as a whole, shows that the temperature never rose

Fig. 2.

PYROMETER RECORD.

above 1,400° F., or fell below 950° F. This record shows good, conscientious, careful firing, such as should ordinarily be obtained in works. Complications are, however, introduced by untoward accidents, which, unfortunately, will happen; and the lower diagram, No. 2, Fig. 2, has been specially selected as indicating the existence of a set of conditions which presented much difficulty.

The record refers to stoves No. 4, 5, 6, and 7, and begins at 10.30 a.m. on February 25th. For  $2\frac{1}{2}$  hours the temperature of the blast rapidly varied between 1,180° and 730° F., and it is evident the working of the furnace showed that it had a "scaffold," and that cold or "coddled" blast was being freely introduced. This state of things continued for 3 hours longer, when the conditions became more equable. It will be observed that when No. 6 stove is resorted to, the temperature suddenly rises, although it is evident that cold-blast was also being used. Stove No. 6 soon gave place to stove No. 7, and the turn of No. 6 did not come again till 7 hours later, when its temperature proved to be very high (1,570° F.), and the same fact was recorded when No. 6 stove was again used at 7.10 a.m. on the following morning. A consideration of this unsatisfactory record led to the view that No. 6 stove must be receiving a supply of hot, and not of entirely cold air during the period in which it was being heated up. It was found, on investigation, that the valve of No. 5 was leaky, and that hot air from the other stoves could find its way into it—an accident which was of course soon remedied.

The importance of maintaining a constant temperature of blast is manifest. The ratio that the reducing actions bear to the fusing ones varies with the temperature of the blast, and if a furnace has been steadily working at a given rate it will be prejudicial to suddenly increase the activity of reduction in the cooler parts of the furnace, as they would then contribute reduced iron and pasty slag at a greater rate than that at which they could be disposed of in the zone of fusion; hence the tendency of the furnace to choke if the temperature of the blast is suddenly augmented.

One of my old students is present, and he will give you the result of his experience in installing the instrument in works, which shows that in certain cases the appliance may do good service in unexpected ways. I have little else to do except to project on the screen a series of slides illustrating specific cases, to which reference can best be made as they are successively thrown on the screen; but I should like to show some photographs recently obtained, and more particularly one which my friend and assistant Mr. Stans-

field secured only this afternoon, of the freezing point of tin. The ordinary freezing-point curve has this form: the temperature of the metal falls until it begins to freeze, then

remains constant. So a curve trace would be a slow fall down to the point when the metal begins to freeze, then a horizontal line during freezing, and then a falling off again when the freezing is complete. But if the angles are sharp, the metal may be considered to be pure. In this case (Fig. 3) you have a remarkable instance of sur-fusion. The line falls 20° below the point of fusion and then suddenly rises, and again falls as the mass cools slowly.

As regards the industrial application of the apparatus, it has been mainly in the relation to metallurgy that the recording pyrometer seems to be useful, and it may be employed in almost every metallurgical operation in conducting which it is desirable to know the temperatures at which products melt or fuse. Is there a copper-smelter who can say that he knows the temperature at which "coarse metal" or "white metal" fuses? However, I am sure that the temperatures are much higher than people usually suppose. In the case of the glass and cement industries, as is indicated by Mr. Redgrave in his book, the appliance would be a most useful acquisition. There must be so many members present who know better than I where and how the appliance would be industrially useful, that I would rather hear what they think than ask them to listen to me any longer.

## DISCUSSION.

Mr. PERCY C. GILCHRIST, F.R.S., was convinced that the beautiful apparatus described by Prof. Roberts-Austen was capable of very wide application. In the metallurgy of steel there were innumerable problems still awaiting the patient investigator. For instance, the difference in temperature between steel hot enough to clear the ladle and make good commercial ingots, and the steel that made skull in the ladle. If an instrument could be produced which could be used by a works foreman for this purpose it would have an almost unlimited application. It would be most interesting to determine the difference in temperature between soft acid and soft basic steel of similar composition as regards Si, C, and Mn. Again, it would be most useful in the Bertrand-Thiel process—a process which he believed would enable one to produce considerably over 100 of steel from 100 of pig—as it would be most valuable to ascertain, as a matter of fact, and not of mere opinion, whether the temperatures employed in these primary and finishing furnaces were different to the temperatures hitherto employed in the basic open-hearth. He would venture to call attention—by no means, however, in opposition to the beautiful instrument described by Prof. Roberts-Austen, but as a tough-and-ready means of arriving at approximate results—to a little appliance which he had brought with him. It was simply a pair of blue spectacles cut into two at the bridge and with a tube each side of the glasses. An observer looking at a piece of red-hot iron with one eye and at iron being welded with the other, could easily calibrate the apparatus; the distance between the two glasses would be a measure of the different temperatures. Again, if one looked on one side at molten pig iron and on the other side at molten steel, one had the data for ascertaining the differences of temperature between the two. He brought this little apparatus forward because it was so difficult to get anyone skilled in the use of the Chatelier pyrometer to go to Austria to register the temperatures used in the Bertrand-Thiel process.

Mr. R. C. STYLES said that the instrument before the meeting was already being put into the hands of gasmen at ironworks, who were able to take the readings and were made responsible for them. Mr. Styles then explained at considerable length the details and trials at various ironworks and potteries where the pyrometer had been instrumental in detecting not only the vagaries of furnaces, hot-blast stoves, and kilns, but also the shortcomings of workmen employed in connection with them. Referring to Mr. Gilchrist's question, he thought that although the temperature of molten steel might affect ordinary porcelain tubes, there would be no difficulty in producing tubes which would stand the test.

Mr. R. FORBES CARPENTER thought that a constant record of temperatures such as this instrument gave would be very valuable in the Deacon chlorine process, as it was most important that the temperature in the decomposers should not get above 1,000° F.

Mr. A. STANSFIELD said that tubes suitable for insertion in molten steel could be produced from fireclay, or graphite and fireclay.

Mr. H. G. GRAVES observed that Dr. Fenning had found that porcelain tubes could be made to withstand very high temperatures by wrapping them with asbestos and filling the inside with powdered tungsten mixed with carbon. Thus protected, even if the tube cracked the asbestos coating would hold it together.

Mr. W. F. REID had made experiments with the resistance pyrometer in the cement industry, but had found great difficulties in the way, owing to the alkaline character of the mass, which had to be tested at a white heat. The resistance pyrometer gave accurate results at certain temperatures, but if one went above them it was not reliable. He would like to know the lowest and the highest temperatures at which Prof. Roberts-Austen had found his pyrometer reliable. For many purposes one might want an instrument which was self-recording uniformly. He would also like to know, approximately at least, the cost of the instrument.

Mr. BERTRAM BLOUNT was certain that manufacturers in many industries would highly appreciate an instrument

that would give a reliable measure of high temperatures. In the cement industry, the very haziest ideas obtained as to the temperature reached in the kilns, and an accurate instrument would be of the highest value to manufacturers. He agreed with Mr. Reid as to the difficulties to be encountered, owing to the nature of the materials employed, but thought that they might be obviated if the tubes were covered by a basic sheath. The most reliable method at present available of arriving at information as to temperatures reached in the cement industry consisted in the use of "Seeger's cones" (little pyramids of mixtures of silicates which softened at various temperatures pretty accurately determined for each mixture). Such a method, however, could not compare for accuracy with the results obtainable by the instrument before them. He would like to ask Prof. Roberts-Austen how he obtained the pure tin to which he had referred in the course of his remarks.

Mr. W. THORP enquired whether the wires were liable to undergo change by prolonged use and especially by the action of gases upon them. Also whether in use they were likely to undergo any mechanical change which would necessitate re-calibration. He agreed with Mr. Reid as to the probable usefulness of the apparatus for giving continuous records of fairly low temperatures in a place distant from the point of observation.

Prof. ROBERTS-AUSTEN, in reply to Mr. Gilchrist's remarks, said that he had made arrangements to send a trained assistant to Austria for conducting accurate measurements, but his plans had been frustrated by the fact that the gentleman engaged had in the meantime been offered other and more remunerative employment. However, the instrument before them was quite at Mr. Gilchrist's service if he would like to take it. He thought there would be no difficulty in determining the temperature of molten steel (taking it to be about 1,500°) if the porcelain tube were encased in one of graphite, as suggested by Mr. Stansfield. The resistance pyrometer of Callendar could be calibrated up to the melting point of gold at least; he had himself, working with Prof. Callendar, calibrated it up to molten silver with ease. He desired to speak in terms of the highest respect of that instrument, and was most anxious that the apparatus which he had brought to their notice that night should not be regarded as a rival instrument. Each was admirable in its way, as had been shown by the work of Mr. Griffiths on the one hand, and Messrs. Haycock and Neville on the other. But if one had a small piece of rare metal it was convenient to be able to put a thermo-junction into it and get its temperature in a way that the resistance pyrometer did not render possible, as, in order to use it, a considerable bulk of metal is necessary. Prof. Dewar was at the present moment employing a thermo-junction for determining those very low temperatures which he had recently attained. For such extreme temperatures on the other side of zero it had been found better to employ the iridium alloy rather than the rhodium. He could not state definitely the price at which the instrument could be produced; the one before the meeting had cost 30*l.*, but it was obvious that economies in its construction could be effected by the use of cheaper materials; and its cost was small when compared with the sums which it had proved itself capable of saving certain manufacturers. It was not patented, and its use, therefore, was at anybody's disposal. Replying to Mr. Blount, if he had used the expression "pure tin" he was only speaking of commercial purity. But bearing in mind the sharpness of the angles of its cooling curve and the dip due to sur-fusion, he thought that it would be admitted that it had a degree of purity which warranted him in speaking of the metal with respect. Mr. Thorp had asked what degree of change the thermo-junction underwent by use; that depended on circumstances. Mr. Stansfield had one particular pet couple which had been carefully used and protected. It had been used up to 1,065°, and in the course of a year had varied only 1° at that temperature.

Mr. THORP said that what he had wished to know was whether a change was produced by prolonged heating rather than intermittent heating throughout a long period.

Mr. STYLES replied that they had used one thermo-couple for six months, but the usual life of a couple was two to three months. No occasion had arisen for recal-

brating them, and the renewal of a wire could be made at a trifling cost.

The CHAIRMAN considered that an instrument such as Mr. Gilchrist had suggested could have but a limited application, owing to the difficulty of obtaining comparative standards of light. He, however, entirely agreed with Mr. Forbes Carpenter that a pyrometer such as had been brought before them must have a wide application in connection with industries such as the Deacon chlorine and sulphuric anhydride processes, in which the reactions which took place were reversible; and would possess great advantages over the resistance pyrometer in that it gave continuous readings, instead of requiring a series of isolated observations. It gave them much pleasure to see the professional element bringing these papers before them, and he trusted that they would have many from the same quarter.

*Meeting held on Monday, January 18th, 1897.*

DR. R. MESSEL IN THE CHAIR.

## THE CHARACTER OF THE LONDON WATER SUPPLY.

BY W. J. DIBBIN, F.L.C., ETC.

THE author has much pleasure in placing before the Society the following results of his experience in regard to the analysis of potable water. As his observations have been more particularly confined to the examination of the character of the water supplied to London, he has naturally taken that supply for the subject of the text, but the main object of the paper is to point out the results of the improved methods employed in the course of the investigation, with the view of submitting them to the criticisms of the Society, as they tend to throw into prominence a point of interest which has hitherto been to a great extent overlooked; this is, that the various matters held in suspension, in presumably pure waters, although small in quantity, are yet often of such a kind as to throw considerable light upon the quality of a sample of water, even after the old methods of analysis fail to distinguish the difference between one sample and another.

For the purpose of recent enquiries into the quality of the water supplied to London, the author has had the opportunity of making daily analyses of the water of the River Thames at the companies' intakes, and of the filtered water supplied by the respective companies drawing therefrom; also of the water supplied by the Kent Company, and by the two companies drawing their supplies from the River Lea and New River.

At first these suspended matters were examined only qualitatively, but it soon became apparent, as the work proceeded, that the quantity was sufficient, if properly collected, to admit of exact determinations, and thus more particularly identify them with the unfiltered river water. The collection was therefore conducted on a much larger scale by subsidence in special glass vessels; but later on it was found that the recently introduced hard filter papers formed an admirable medium by means of which the solid particles could be collected each day and treated with a dilute solution of bichloride of mercury to prevent decomposition, until their microscopical examination, as well as chemical analysis. By this means not only the quality, but the exact quantity was estimated, and thus further light was thrown upon the much vexed question of the analytical examination of water. A modification of this method, in which a specially constructed micro-filter\* is employed, has enabled determinations of the relative quantity, in terms of volume instead of weight, of the suspended matters to be made on quantities of water too small even for an ordinary analysis. The results of this method are embodied in the table of analyses under the head of "millimetres of suspended matter in micro-filter from one litre of water."

This process was a development of that adopted for collecting the floating particles for the purposes of microscopical examination, and by this means insuring the inclusion of the total number of such particles under one cover glass, thus insuring greater rapidity as well as accuracy.

Previous to this enquiry it does not appear that any such quantitative methods had been employed. It is clear that either vegetable or animal substances may be qualitatively indicated in terms of carbon, nitrogen, ammonia, and so forth; but such methods of expression, though valuable under certain circumstances, convey but little idea of their relative character, or whether they are in a fresh and wholesome condition or in a state of putrefaction.

In the course of some evidence given by the author before the recent Royal Commission on the London Water Supply, he made the following observations:—

"You may have in a tube of water a few floating particles, and when you have carefully isolated these you will find that they are made up of fibres and a number of organisms, and so on, and occasionally a microscopical cell, all of which would tend to show inefficient filtration or storage, as the case may be. Of course, we know that it is with the greatest possible difficulty that you can keep these things out, but, nevertheless, we do not get them (to anything like the same extent) in the Kent Company's water. If the filtration is so efficient as to take out 99.9 per cent. of the organisms of far more minute microscopical organisms than some of these, how is it that these bigger ones get through? It is a matter of surprise that if the filter is of sufficient mesh to stop a marble, how is it that a cannon ball gets through? These things point to the necessity of a more systematic examination of the London water supply. At the present moment London is in a very peculiar position with regard to its protection. In the case of the gas companies, their gas is examined nightly at no less than 23 gas-testing stations, and they are subject to forfeitures in case their gas is below a definite standard; in the case of the water companies, one sample is taken per month, and if it is good, bad, or indifferent it does not seem to matter; no notice is taken. It has often been a matter of surprise to me why there has not been a systematic examination of the water, with such consequences ensuing to the companies as might be considered proper and just if they failed through any neglect. I do not say failed in any case, because it might be an accident, but if they failed through neglect, then they ought to be subjected to the consequences in the same manner as the gas companies are. If in the matter of what concerns our pocket alone—in the matter of gas—it is necessary to have such very strong and stringent precautions as we have, surely one would think that in the matter of water it would be equally advisable that equally good supervision should exist."

In the report of the Commissioners the following observations occur:—

*"As to the Treatment of the Water after its Abstraction from the River.*

"We have further to consider what steps should be taken to ensure the proper treatment of the water that is taken from these rivers for the supply of London. For the water that flows down these rivers must be subjected to certain important processes before it is brought into suitable condition for delivery and consumption. These processes consist of subsidence and filtration, and the quality of the water when delivered depends largely upon the thoroughness with which they are carried out. It does not come within the terms of our reference to lay down what should be the exact regulations as regards filtration, that is to say, what should the proportionate area of the filtering beds, the depth of sand, the frequency of renewal, or the rate at which the water should be allowed to percolate; nor, as regards the subsidence tanks, how many days' storage should be deemed sufficient so as to obviate the necessity of taking in turbid storm water, and to allow of due settlement; but we cannot shut our eyes to the fact that the provision for these purposes differs enormously in the different companies, and in some of them is, to our mind, quite inadequate."

This very pronounced opinion of the Commissioners left no possible doubt as to the correctness of the views placed before them in the above extract. Unfortunately at that time there was no information available as to the exact quantity of matter held in suspension in the water; but the work which has since then been undertaken has enabled this point to be most satisfactorily settled, and we are now in possession of reliable data on the point. As will be

\* *The Analyst*, January 1896.

seen later on, one of the most satisfactory features of the case is that, while there can be little doubt as to the correctness of the position thus authoritatively laid down in 1893, the improvement which has been effected by the companies since that time has been most marked, and leaves not a shadow of a doubt as to the correctness of the opinion that the companies could and should effect better work in purifying the water from contamination. So far, good; but

what guarantee is there that when the present interest in the question is less keen, the condition of things above indicated will not return, unless there is kept up a thorough and complete daily examination of the water supplied by each of the respective companies.

The average results of daily analyses during nearly 12 months ending December 1895, gave the following quantities of suspended matter, in terms of grains per gallon:—

		Grains per Gallon.		
		Mineral.	Volatile and Organic.	Total.

It will be noticed that the average quantity of suspended matters present in the Kent, West Middlesex, and New River supplies were practically identical, namely, 0·0011, 0·0010, and 0·0011 grain per gallon respectively, so that the West Middlesex Company found it possible to so purify and store the water, that in this respect it bears comparison with waters which are generally accepted, in view of their source, as beyond suspicion. This quantity may therefore be looked upon as that unavoidably due to rust and dust, and forms a standard whereby to judge the quality of the remaining supplies. Taking the average quantity of suspended matter found during this enquiry in the water supplied by the Southwark, Lambeth, Chelsea, Grand Junction, and East London Companies as 0·0033 grain per gallon, and deducting therefrom the 0·0011 unavoidable or rust and dust matters, found as above, we have 0·0022 chemically dry grain per gallon as obviously avoidable suspended matters present in the filtered water supplied to consumers. In order that this average factor may be more readily grasped, we may convert it into terms of "mud" of 90 per cent. moisture (the usual percentage present in such matter) actually supplied per annum. Thus the volume of river water supplied by these companies is 131·6 million gallons daily, so that the quantity of avoidable suspended matters present in that supply is equal to 67·5 tons of wet mud per annum. This, however, includes the period during which the suspended matters were at their lowest. If, on the contrary, the estimation is made on the basis of those present in the Southwark Company's supply during the month of April 1895, namely, 0·0385 grain per gallon, the annual average would be equal to 1145 tons.

How far this factor would have been increased had such estimation been made during the bad season of November and December 1891, it is difficult to judge, as such estimations of the suspended matters were not then made; but from the improvement effected in the colour of the water, as well as in its analytical character, it is open to the assumption that the suspended matters largely exceeded those present during 1895, and thus enormous quantities of river *débris* must have been distributed throughout the metropolis during every flood period.

I would direct attention to the new method of estimating the relative volume of suspended matters by means of the micro-filter, which enables such estimations to be made on small samples of water, instead of on many hundreds of gallons, as was the case with these results given in actual weights. Comparison with the gravimetric method shows that for practical purposes the new micro-filter method gives identical results, with the further advantage that the sample is immediately ready for microscopical examination.

The table on page 11 shows the relative quantity of suspended matters present in the various supplies when determined gravimetrically and by the micro-filter, the numbers representing the monthly average of daily estimations.

From that table it will be seen that there is clearly an indication of the quality of the suspended matter from the ratio of mm. in micro-filter per litre of water to grains of actual suspended matter per gallon; thus the average of the Kent Company's water for the six months ending November 1895 gave a ratio of 0·0023 grain per gallon for each mm. in the micro-filter; in like manner the New River Company showed a ratio of 0·0033; the West Middlesex, 0·0022; the Chelsea, 0·0052; the Grand Junction, 0·0057; the East London, 0·0042; the Lambeth, 0·0052; the Southwark and Vauxhall, 0·0056; and unfiltered Thames, 0·0633. From this it is seen that when the water is "purer," the weight of suspended matter per unit volume is least—a fact which is evident on microscopical examination; as in the purer waters only a few fibres with a little *débris* were generally present, in contrast with numbers of particles of *débris* and decaying organic matter, with numerous diatoms, &c. in the case of those waters which bear the least resemblance to the Kent.

From a consideration of these tables, another instructive fact is apparent, *viz.*, that the quantity of deposit in the micro-filter becomes referable, within useful limits, to the actual weight found by a gravimetric process of estimation; thus the average depth of deposit in the micro-filter was 0·44 mm. per litre of water, and the average weight of suspended matter found by the gravimetric measurements was 0·0019 grain per gallon, and therefore 1 mm. of deposit from a clean water in the filter equal to 0·0042 grain per gallon. Experiments are now in hand with the view of showing, if possible, that a scale may be used by means of which the micro-filter results may be directly compared with the gravimetric ones now usually made in the case of sewage analyses, &c.

In the course of 12 months' determination of the quantity of suspended matters present in the Kent Company's supply during 1895, I found that the average was 0·0011 grain per gallon. This quantity I have ascribed to unavoidable rust and dust, and it may be safely concluded that any suspended matter less in quantity than this amount may be neglected as of no importance.

Looking to the above comparisons of the estimations by the micro-filter and by the gravimetric method, 0·0011 grain per gallon may be taken as representing one-fourth of a millimetre per litre in the micro-filter; we thus have a standard of comparison which may be usefully employed in such determinations, and we may therefore conclude that if the depth of deposit from 1 litre of water in the micro-filter tube of 2 mm. diameter does not exceed 0·2 mm., it may be safely neglected, unless the microscopical examination reveals the presence of definitely objectionable particles.

My own experience with many waters leads me to think that no serious notice need be taken of any quantity less than 1 mm. per litre, equal to 0·004 grain per gallon, as shown above, or even a larger quantity, unless it is observed there is a definite microscopical evidence of objectionable

contamination and the chemical analysis shows a questionable state of things.

The chemical examination of the character of the suspended matter gave very remarkable results. For the purpose of this comparison the dry matters obtained from the water, either by natural subsidence or filtration, were examined for the nitrogen present in combination with the organic matter. The average percentage quantity found is set out in the following table:—

*Nitrogen per Cent. on Volatile Organic Matter.*

Chalk.....	Kent.....	2.12
	Southwark.....	3.41
	Lambeth.....	3.42
Thames.....	Chelsea.....	2.97
	Grand Junction.....	3.66
	West Middlesex.....	2.86
New River.....	New River.....	2.86
Lea.....	East London.....	2.97
Thames Intakes.	Sunbury.....	1.06

For comparison, the following results of the estimation of the quantity of nitrogen present in known samples of polluted mud are given:—

Sewage mud.....	5.20
Known polluted river mud.....	1.40
Pure river mud from the Fitzroy River, Queensland..	2.70

They clearly point to the conclusion that the suspended matters present in three of the companies' filtered supplies approximated more or less nearly in character to those in the unfiltered river waters at the companies' intakes.

*Microscopical Character of the Suspended Matters.*

The conclusion drawn from the consideration of the relative chemical character of the suspended matters in the unfiltered river water, compared with those in the filtered supplies, is borne out by the results of the daily microscopical examination of all samples collected, the average results of which are set out in the following condensed table:—

*Percentage Number of Samples returned as "Objectionable" \* by the Microscopic Examination.*

	Samples examined.	Returned as Objectionable.
		Per Cent.
Kent.....	284	18
Southwark.....	286	47

Grand Junction.....	285	25
West Middlesex.....	285	24
Average.....	..	30
New River.....	286	21
East London.....	283	30

\* "Objectionable" samples are those which contained a comparatively large quantity of *débris*, microscopic eels or anguillulae, &c., decaying *débris* infested with bacteria, the larger infusoria, such as paramecium, rotifera, &c., epithelium scales, &c.

These percentages were then calculated into total quantities of objectionable matter present on the actual

estimation of the weights of suspended matters found, and are thus set out in column 4 of the following table :—

\* NOTE.—The microscopical examination includes with the organic, the mineral matter, which is proportionately larger in the case of the intake waters than in the filtered supplies; hence the objectionable matters appear to be greater by the microscopical examination than those estimated by the nitrogen, which relate solely to organic matter.

The practically complete coincidence between the various methods of examination—namely, the physical, as the estimation of the weight of the suspended matters may be called; the chemical and microscopical examination of their character; the biological examination as to the actual number of bacteria present in a given sample of water; and the strictly chemical examination as to the quantity of oxidisable organic matters dissolved in the water—is very striking.

The unfiltered river water contained a mass of matters of generally indefinite character included under the head of *debris*; but, in addition to these, certain noticeable features were distinct, amongst which the diatomaceæ were predominant; entozoic worms, various dyed and undyed textile fibres, such as wool, cotton, silk, &c., were not infrequent; together with numerous infusoria and bacteria.

The results of the examination of the filtered supplies indicated the frequent presence of all these substances, and in the majority of cases it would have been difficult for a careful observer to conclude from the examination of the preparation under the microscope whether it was drawn from the unfiltered river water or from one of the filtered supplies (it being understood that the actual quantity of *debris* taken for examination was equal in each case). Diatoms were almost always present, and not infrequently anguillulæ also; but the most noticeable and objectionable feature was the frequent presence of fragments of matter in a state of decomposition and swarming with bacteria. The presence of such particles cannot be accepted as inevitable in the case of a pure water supply, as, if the filter beds are properly worked, it should be impossible for such matters to pass them, whilst if their presence be due to dust getting into the pure water reservoirs, evidently greater care should be taken to keep them clean. That a particle of dust might be so introduced is not to be doubted, in view of the fact that on a few occasions the Kent supply was found to contain such matters in small quantities, but evidently accidentally so, as compared with their more frequent presence in larger quantities in the filtered river waters.

From the results of the work now put on record before this Society, it is clear that much more may be learnt from the proper collection and examination of the suspended matters, however small, in a sample of water than has hitherto been supposed, and the author ventures to suggest that in future all samples of waters should be so examined.

A great point has been made in recent years of the number of bacteria present in a water, but from the experience now obtained it would seem as if the number of bacteria depended more upon the quantity of suspended matter than on any other factor.

Considerable differences have been obtained in the estimation of the number of bacteria by different observers. It would now seem possible that these differences are occasionally due to the fact that in one sample certain particles of decaying matters may have been present, although absent in another—a result which would account for many hundreds, if not thousands, of colonies being obtained by one experiment, and but few by another, quite apart from the known differences due to varying methods of procedure, temperature, &c.

#### Bacteriological Examination.

The examination of the daily samples of water for the number of bacteria as determined by the number of colonies developed on gelatine plates, has yielded interesting results, and affords further evidence of the improvement effected in the various filtered supplies.

On page 13 is given a condensed tabular statement of the monthly average number of microbes present in the water collected from stand pipes in various parts of the respective companies' districts.

Having thus reliable data for comparison as to the bacteriological improvement which has taken place in the quality of the water between the years 1892 and 1895, it will be interesting to glance at the still further improvement which took place during the course of the latter year, and of the relation which exists between the quality of the intake waters and the filtered supply.

It will be noticed that the company which supplied water containing the largest quantity of suspended matters—*viz.*, the Southwark and Vauxhall—supplied an average of 352 microbes per cubic centimetre of water throughout the year, this being the largest number of any of the companies. In January, the monthly average was 838, which gradually decreased with the reduction in the quantity of suspended matter during the year to 78 in October, but, unfortunately, rose again to 427 in November, corresponding to the rise of microbes in the Sunbury river water of from 9,900 in October to 45,263 per cubic centimetre in November.

Average .....	90	352	294	130	170	130	130	277	16,061

In 1891-92 the following average results were obtained :—

4,795	1,591	1,626	3,061	2,612	2,534	2,299	3,387	179,601
-------	-------	-------	-------	-------	-------	-------	-------	---------

The relative value of the various methods of estimating the organic matter in water—*viz.*, the organic carbon and nitrogen or "organic elements," the albuminoid ammonia, and the oxygen absorbed—has been observed in connection with the series of analyses under discussion. The results of 12 monthly averages of daily analyses made during 1892 (which period is selected in preference to 1895, when there was a break in the continuity of the analyses as regards organic elements and albuminoid ammonia) has shown that the oxygen-absorbed method, as used by the Society of Public Analysts, has been found to give the most concordant factor all through. In the case of waters of known origin, such as those supplied to London, it does not appear to be necessary to repeat indefinitely processes which, however valuable in themselves for certain purposes, fail to throw any fresh light upon the general history of the water.

*Comparison of the present London Supply with the proposed Supply from Wales.*

In order that the exact position of the present supply may be clearly understood, so far as regards the question of relative quality and the extent to which an improvement might be anticipated in the event of the Welsh water being brought to London, I submit the following considerations arising from the comparison of the analyses of the water at present supplied to London with those of the Welsh waters collected by myself in May 1894.

In the following table the analytical factors in each case are placed side by side, so that the specific differences may be seen at a glance. The figures representing the Welsh waters are averages of the samples drawn from the rivers Usk, Edw, Yrfon, Wye, Towy, Ithon, and Glywedog, which were, of course, unfiltered. Those representing the present filtered river water supplied to London are averages of the Southwark, Lambeth, Chelsea, Grand Junction, West Middlesex, and East London. These, however, are given in two columns, one for average summer quality, and the second showing average winter quality. For comparison as a standard, the Kent Company's average supply is added.

On carefully examining the results it will be found that the filtered river water supplied during the six summer months to London contains practically identically the same amount of organic carbon and nitrogen as that present in the unfiltered Welsh waters, *viz.*, 0.128 part per 100.000 against 0.123, whilst during the six winter months it is only half as much again, *viz.*, 0.199.

The oxygen absorbed from permanganate is a little more, *viz.*, 0.057 during the summer instead of 0.048, but only a little more than half as much again, *viz.*, 0.079 grain per gallon during the winter. In like manner the "albuminoid ammonia" in the Welsh water averages 0.0033 against 0.0045 and 0.0055 in the respective summer and winter London supplies excluding the Kent. The colour of the water when viewed through a 2-ft. tube was on an

average even more in the case of the Welsh water, *viz.*, 1.4 against 1.0 and 1.2 in the case of the London supplies.

From this comparison of the average results of nearly three thousand analyses, it is evident that the organic impurity of the unfiltered Welsh water is a little less than that in the average filtered London water, and the inquiry naturally follows as to the specific differences which exist. This is undoubtedly due to two things: first, the quantity of the solid matter in solution, principally salts of lime, giving the London water its greater hardening properties; and second, the comparatively large quantity of floating particles, on which, as has been shown, the number of microbes present to a great extent depends.

The unfiltered Welsh water examined on the spot contained 26 microbes per cubic centimetre, whilst the average London filtered waters contained in summer 167 and in winter 298, the Kent supply containing 90. Of course, it will be noted that these numbers refer solely to the quantity and not to the character of the microbes.

#### *The Effect of Softening the present Supply.*

The suggestion has been repeatedly made that the excessive quantity of lime in the London water should be removed by the adoption of the well-known Clarke's process, and it is only natural to inquire as to what would be its effect upon the present filtered river water, not only in removing the excess of carbonate of lime, and thus effecting an enormous improvement in the commercial value of the London water, but also in assisting in the process of purification. With the view of testing this question certain experiments have been made on one of the best London

waters, *viz.*, that of the New River Company, in order that the percentage reduction, if any, which might be brought about in the quantity of dissolved as well as undissolved impurity might be ascertained.

The results of these, which are stated in the table below, are perfectly definite, and show that even in the case of the New River supply the reduction of dissolved organic impurity was equal to 25 per cent., as shown by the oxygen absorbed, whilst 64 per cent. of the total hardness was removed and 87 per cent. of the bacteria, and with these the whole of the matters in suspension. If one of the less pure waters had been taken for this experiment, such as the Lambeth or Southwark, doubtless the percentage reduction of impurities would have been larger.

On applying these results to the average analytical figures given in the table, it will be found that the "albuminoid ammonia" in the summer supply would fall by the adoption of the process of softening from 0.0015 to 0.0034, or identically the same quantity as that in the unfiltered Welsh supply, whilst the winter supply would be improved to the quality of the present summer supply; that the oxygen absorbed in four hours would fall from 0.057 to 0.043 in summer, and from 0.079 to 0.059 in winter, against 0.048 in the Welsh water, or a yearly average of only 0.003 grain per gallon in excess; that the organic carbon and nitrogen would be less in proportion, whilst practically the whole of the "suspended matters" would be removed, and with them 87 per cent. of the bacteria, thus reducing the summer number (apart from their character) of microbes from 167 to 21, and the winter from 298 to 38, against 26 in the Welsh water, or an annual

average difference of + 3. In addition to these enormous improvements the hardness would be reduced in summer from 12.5° to 1.1°, and in winter from 17.0 to 6.1, or an annual average of 5.2°, against 3.1°, which was the average hardness of the Welsh waters as examined in May 1894.

It would therefore seem that by the adoption of the system of softening, the present supply, in respect of its chemical quality and number of bacteria, would be improved to a degree comparable with that of the Welsh sources.

The discussion on this paper stands adjourned until February 15th.

## ON A NEW METHOD FOR THE RAPID VALUATION OF ZINC DUST.

BY ANDRÉ R. WAHL.

Zinc dust is a body in very extensive use as a reducing agent, especially in vat indigo dyeing, and in the manufacture of certain colouring matters. For these purposes, especially in the latter, where the reductions performed are very delicate operations, requiring theoretical proportions of the materials, it is very important to know the actual value in metallic zinc of the zinc dust employed. The methods at present in use are either unreliable or require much time to perform, and I have therefore been led to seek a method at the same time both exact and rapid, and consequently especially suitable for commercial application. The principle which I have employed, and which entirely fulfils these conditions, is the reduction of a ferric salt and subsequent titration of the quantity of ferrous salt produced.

I have found that when solid ferric sulphate is added to zinc dust suspended in a little cold water with exclusion of free acid, a reaction occurs with evolution of heat, and the zinc quickly and totally dissolves with formation of a clear greenish solution. A small residue remains consisting of lead and other impurities. The solution of the zinc takes place without any evolution of hydrogen, and the reaction is therefore represented by the equation—

When all has dissolved, it is only necessary to acidify the solution with sulphuric acid and titrate with permanganate

to find the quantity of ferrous salt obtained, and hence the quantity of metallic zinc in the sample under examination.

**Procedure.**—(a.) *Preparation of Pure Ferric Sulphate.*—500 grms. of pure ferrous sulphate are dissolved in as little water as possible, and to it are added 100 grms. of sulphuric acid and 240 grms. of nitric acid (60 per cent.). On adding the nitric acid, torrents of nitrous gas are evolved, the solution acquiring a nearly black colour, which disappears again when the whole of the acid is added. The solution is evaporated on the water-bath until it becomes solid, when it is ground with alcohol in a mortar, put on a filter, and washed with alcohol until the filtrate is no longer acid. The product is then dried thoroughly on the water-bath, and the salt, which is a perfectly white powder, is kept in stoppered bottles for use.

(b.) *Analysis.*—About  $\frac{1}{2}$  gm. of zinc dust is put into a stoppered 250 c.c. flask and to it are added 25 c.c. of cold water. The mixture is agitated, and when the zinc is thoroughly suspended, 7 grms. of ferric sulphate are added. There is a gentle evolution of heat, and after shaking for a quarter of an hour, the zinc will have completely dissolved, with exception of a slight residue of impurities. 25 c.c. of strong sulphuric acid are then added, and the flask is filled with water to 250 c.c. 50 c.c. of this solution, after dilution with 50 c.c. of water, are titrated with standard permanganate.

From the quantity of the latter employed, the percentage of metallic zinc is at once found.

The new method gives results which agree with those obtained by Drewson's method, *viz.*, reduction of chromic acid. Thus for a certain sample of commercial zinc dust the following numbers were obtained:—

	New Method.	Drewson's Method.
I. ....	85.5	84.8
II. ....	85.4	84.5
III. ....	85.5	..

The new method has, however, the advantage of being extremely simple and rapid; it only requires a standard solution of permanganate, a reagent found in every commercial laboratory, and lastly, since the end point is indicated by the pink colour of the permanganate, the titration is sharper than in the method of Drewson, in which a spotting test is employed. To obtain accurate results it should be borne in mind that the ferric sulphate, if not well dried, may sometimes retain a trace of alcohol, which would reduce a little permanganate. It is therefore better to perform a blank experiment with the same quantity of ferric sulphate as used in the analyses and deduct the amount of permanganate reduced from that found.

### DISCUSSION.

Dr. GROSSMANN said that the method described in the paper might be more convenient than the method of titrating with bichromate as generally used, but it suffered from the same defects as the chromate and other methods. First of all, they did not consider the fineness of the zinc powder, which had a great deal to do with its commercial value. Secondly, they did not show any quantity of iron present as such. There was nothing to prevent anyone from grinding iron filings up finely and mixing them with zinc dust, and none of these methods would show that. This method, as well as the older ones, therefore, would open a field for adulteration.

Dr. LEWKOWITSCH said he had used this method some 16 years ago in an analytical laboratory, but he did not publish it as he thought it was not new.

Mr. BARNES (Borough Analyst, Accrington) said the writer of the paper described a method which he (Mr. Barnes) published about 11 years ago\* as a rather tedious process. He did not find it so, as several tests could be made at once by having a number of graduated tubes, in which the

\* This Journal, 1886, 145.

hydrogen was collected, and by using one with a standard zinc all corrections for temperature and pressure were avoided. It was possible that iron might be measured as zinc in this process, as in titration by permanganate, but he did not think that was of much consequence, because metallic iron could be determined in a separate test by permanganate, or might even be removed by the magnet.

Mr. HARRY GUNSHAW said, from his own experience, he was of opinion that Mr. Barnes's method was decidedly quicker than the one set forth in the paper. He did not think any chemical method could very well give the difference between the respective fineness, which, of course, was an item of commercial value. A few years ago he had tried a kind of ground zinc, but found it was not suitable for work solely on account of not being in a sufficiently fine state of division.

Mr. GREEN, in replying on behalf of Mr. Wahl, said that all the methods of estimation of zinc dust at present in use were open to the objection of showing iron present as if it were zinc, but he did not consider this of much importance. A large quantity of iron was not of common occurrence, and if present could readily be estimated. No process could be expected to give satisfactory results with a zinc dust containing coarse lumps, and such a product would be useless for the purposes for which zinc dust was employed. The method of evolution and measurement of hydrogen employed by Mr. Barnes, besides being somewhat troublesome, was open to the objection that the lead was shown as zinc, whereas in Mr. Wahl's method lead remains undissolved. What was required in a commercial method of estimation was a process, readily and quickly performed, which would accurately indicate the reducing power of a given sample of zinc dust when used in alkaline or neutral solution; and Mr. Wahl's method fulfilled these conditions.

#### ON THE PROPOSED NEW SCHEME FOR DEALING WITH THE MANCHESTER SEWAGE.

BY WILLIAM THOMSON, F.R.S. ED., F.I.C.

THE treatment of town sewage is at the present moment a question of supreme importance to the people of Manchester, and I have undertaken to commence a discussion upon the definite scheme which has now all but received the sanction of the Corporation.

The scheme is this: that the Manchester sewage be purified by precipitation, and that the effluent be conveyed by a tunnel some 10 miles in length to Latchford, and there poured into the River Irwell, *i.e.*, the Ship Canal. The estimated cost of this conduit is somewhere about 200,000*l.*, and it must not be forgotten that, if the experience gained in the construction of the Manchester Ship Canal goes for anything, it is probable that a great increase on the estimated expenditure may be anticipated before the work is completed.

To one who has not followed the arguments put before the City Council the scheme appears an extraordinary one. The river has been receiving up to the present time a large portion of the untreated sewage of Manchester and other townships on its banks. Now Manchester has resolved to purify all its sewage by precipitation, which will give a tolerably pure effluent. The further purification of this effluent will, however, entail an enormous cost on the inhabitants, and it is suggested that a conduit be constructed to run this purified sewage into the river 10 miles below Manchester. This looks as if the sewage, after being greatly purified by precipitation, were more objectionable than the raw sewage. This development of the sewage question is consequent upon the Joint Committee refusing to be satisfied in the first instance with an effluent produced from the sewage by precipitation alone, although, so far as they know, it may prove satisfactory as regards freedom from sediment and putrid odours during warm weather.

It has hitherto been considered by the supremely practical people of Manchester that great and costly undertakings should be carried out by processes of natural development, and that no step be taken which is not absolutely necessary; but in this scheme we are asked to make two steps at once, each of them involving large expenditure. The Corporation

has given its provisional vote for both steps to be taken at the same time, and one may assume therefore that a strong case has been put before it. We must therefore look to the origin of the scheme to find how it came to be presented, because there can be no doubt that, from the premises set forth, the conclusions at which the Corporation arrived were correct.

Sir Henry Roseoe propounded the statement, which has been taken by the Mersey and Irwell Joint Committee, that it is impossible to obtain a satisfactory effluent from the Manchester sewage by precipitating the suspended matter and a large quantity of the soluble organic matter from it by means of sulphate of iron and lime; and with a view of making it satisfactory he advised the further treatment of the effluent by one of two methods: (a) By pouring it into filters composed of ashes, coke breeze, or sand, and then leaving it for a time sufficient to allow bacteria which were there cultivated to eat up or further oxidise a great portion of the organic matters left in solution; or (b) that the effluent (obtained by precipitation) should be filtered through land.

At this stage it came under the consideration of the City Surveyor, who treated the question from this point of view in a extremely able and practical manner. He calculated the cost of either or other similar filters and the working of them, and took into account their liability to become choked and the probable cost of cleansing and repairing for the one scheme; and he calculated the area of land required for filtration, and the cost of working, &c.; and after taking into consideration the liability of the land to become inoperative, the difficulty of finding land, and the cost of pumping which would be required for some of the land which was available, he finally himself propounded a third scheme, which would be much less costly than either of the others, *viz.*, to construct a conduit to take the whole effluent into the river 10 miles below Manchester.

Assuming one of the three above-mentioned alternatives to be absolutely necessary, the last scheme is undoubtedly the best, if the Mersey and Irwell Joint Committee will be satisfied with it; but, so far as I can understand, it is not by any means certain that they will; and it has power to prevent pollution at this point as well as at any other on the stream or canal.

The crux of the whole matter lies in the premise which led to the serious consideration by the Council of these three schemes, *viz.*, that the sewage, after being treated by precipitation and simple filtration, is unfit to pass into the River Irwell or the Ship Canal.

Now from a common-sense standpoint in deciding what kind of effluent is satisfactory for passing into any river, the nature of the river must be considered. The River Irwell ceased to be a fishing stream probably 50 years ago, and since then it has practically become an open sewer for Manchester and Salford, and the townships higher up on its banks. It must be conceded that to reconvert the Irwell into a fishing stream would be to make those who live near it expend probably 100*l.* for every penny which could be obtained through the value of the fish which could be taken from it, and I think no one would seriously argue that this should be done. Then for what reason are we called upon to purify the river? It cannot be shown that those who live along its banks suffer from zymotic diseases to a greater extent than those who don't. The answer to this question is obvious: the river must be purified to the extent, first, that it will not become silted up to any extent, and secondly, that it will not be a nuisance to those who live near it or who are in boats sailing upon it. In my opinion both of these reasons may be taken as one, because the putrid odour which emanates from the canal in warm weather comes chiefly from the fermentation, decay, or decomposition of the organic matters of the raw sewage which settles to the bottom.

The problem should therefore be this: Is it possible to treat sewage simply by precipitation, or by precipitation and simple filtration, so as to prevent it from throwing down a sediment capable of putrefaction, and so that the organic matters left in it will not themselves emit a putrid or objectionable odour on being kept for, say, two or three weeks in warm weather, or, more accurately, for such

time as the water remains stagnant in the Ship Canal? I believe it is possible to do this by one or other of several precipitation processes, and I think this should be practically tried during one or more years before Manchester is called upon to expend immense sums of money for the further treatment of its sewage. This, however, is not the criterion of the Mersey and Irwell Joint Committee. They have taken the working chemical standard laid down by Sir Henry Roscoe more seriously, I think, than he intended, *viz.* :—

(1.) That the effluent should not contain more than  $\frac{1}{10}$ th of a grain per gallon of suspended organic matter;

(2.) That it should not yield more than 0.1 grain of albuminoid ammonia per gallon; and

(3.) That it should not require more than 1.0 grain per gallon of oxygen derived from potassium permanganate to oxidise the matters contained in solution.

It might be argued that town sewage effluent containing more than the quantities suggested by the Joint Committee would decompose and emit objectionable odours; but the sewage of different towns differ from each other very materially, and I have seen no record of any test made with any effluents obtained from Manchester sewage by precipitation, which proved that none of them would keep for two or three weeks in warm weather without emitting a putrid or objectionable smell. On the contrary, I have myself kept samples of effluents obtained from the sewage of both Manchester and Salford for many weeks without their emitting any putrid or unpleasant odour. Here is a sample produced by one precipitation process from Manchester sewage which I have kept in a warm room for two months, and it has remained during that time free from objectionable smell; and I think Mr. Carter Bell will bear me out as regards the keeping qualities of most of the effluents produced by the precipitation processes worked in connection with the Salford sewage. I have some samples of the effluents obtained by perhaps the simplest of all, *viz.*, the addition of about 16 grains of lime per gallon of sewage; this gives a copious precipitation. The precipitate settles rapidly, and the effluent, without filtration, was comparatively clear. The effect of the lime on the effluent was to produce a faint characteristic smell, not unpleasant, resembling to some extent herringbrine, but this smell did not increase nor alter during many months, and the effluent on being kept warm did not undergo decomposition. It has frequently been stated that effluents from the lime process of purification do undergo putrefaction, but I think this takes place when a much smaller quantity of lime is employed. It has been suggested that although the effluent may not emit objectionable odours when kept by itself, that it will putrefy when mixed with the waters of the Ship Canal; but it is difficult to understand this statement, because the waters of the Ship Canal will emit a putrid odour, whether or not you mix it with a sewage effluent, if samples of it be kept in a warm place for some time.

If we assume that effluents produced by precipitation are capable of entering into decomposition and evolving putrid odours when kept in a bottle or vessel in a warm room for some days, weeks, or months, it does not follow that if the same effluent were poured into the Ship Canal that this putrid decomposition would go on under those conditions. The point upon which I wish to be specially emphatic is this: that part of the scheme which is now before the Corporation is to purify the waters of the Ship Canal in the best possible manner by chemical means, *i.e.*, by precipitation and subsidence or filtration; and it seems extraordinary that an experiment should not be made to observe whether the smell during warm weather is not greatly reduced or entirely removed, and thus determine directly by that means whether such an effluent is or is not fit for passing into the Ship Canal before expending further large sums of money.

The result must certainly be a distinct improvement, and it can certainly not be worse than it was previously.

It has been suggested that Manchester is bound to produce a purer effluent than that which can be done by precipitation, as an example to manufacturers and

smaller townships up the stream. Let us look at the nature of the example which Manchester proposes to set.

The Act of Parliament says that "every person who causes to fall or flow into any stream solid or liquid sewage shall be deemed to have committed an offence under the Act," but it goes on to say the person causing the sewage so to fall or flow shall *not* be deemed to have committed an offence against this Act if he shows to the satisfaction of the court having cognisance of the case that he is using the best practicable and available means of rendering harmless the sewage matter so falling or flowing into the stream.

The Manchester Corporation might improve the effluent obtained from precipitation by means of filtration through coke-breeze or cinders, or by the process which was regarded by the Joint Committee as the best of all, *viz.*, by filtration through land. The latter would involve, according to the City Surveyor's calculations, the purchase of about a ninth part of the whole area of Manchester for the purpose of treating the 26,000,000 gallons of effluent with which it has to deal. If the proposed scheme be carried out, the example which will be shown to manufacturers and to the smaller townships higher up the stream is that they have abandoned the idea of further treating their effluent as impracticable, and as an alternative have carried it by means of a conduit nearer to the tidal waters of the river. If this example means anything it means that the best thing which the manufacturers and townships higher up the stream can do is to follow it and to make for themselves other conduits for the same purpose. This method, however, can hardly be called a practicable one, and I am afraid that if all the manufacturers and townships up the stream were to follow this example there would be very little water left for the Ship Canal, and it is probable that the owners of the Ship Canal would much prefer to be supplied with the crude sewage than have the effluent removed by conduits in the manner proposed by Manchester.

It seems to me in carrying out such Acts of Parliament that the method employed by the late Dr. Angus Smith under the Alkali Act is the one which should be employed by the Joint Committee for dealing with the river, *i.e.*, to allow the purification methods to develop slowly. We know that the treatment of sewage with iron or alumina and lime or some similar process very materially improves the quality of the effluent. Why should the authorities not insist upon all those on the watershed employing an efficient precipitation process? If the whole of the water passed into the Ship Canal reached this standard of purification, I think a most remarkable diminution would be observed in the putrid odours evolved during warm weather. Experiments might be carried on by different manufacturers on the watershed, or by the chemists and engineers connected with the Mersey and Irwell Joint Committee, or by the Corporations of Manchester and Salford, to find a better method of dealing with the question.

The matter stands at present in a most unsatisfactory position, because the Joint Committee are not satisfied with precipitation processes, and their dissatisfaction is, I believe, based chiefly upon laboratory experiments. It must be taken into account that the greater the pressure put upon manufacturers to purify their sewage, the greater will be the loss to Manchester, and it seems obvious that such pressure should be applied in the most careful manner possible.

I understand that manufacturers and the smaller townships have been required to treat their effluents by land filtration, and have had to buy land at exorbitant prices for the purpose of complying with the standard. It appears to me that, if such conditions are to be made, Acts of Parliament should be framed with a view to compel landowners to sell the necessary land at something like agricultural or twice agricultural value.

#### DISCUSSION.

Dr. PANKHURST expressed surprise that the Manchester Corporation had not taken the advice of chemical experts on the subject of the sewage effluent, and contended that

had they done so they would never have been placed in the difficult position in which they now found themselves. It was to be deplored that when a great public body was embarking upon a large expenditure it did not supply itself in the first instance with scientific aid. He was satisfied that if crude sewage were prevented from entering the Ship Canal and a good system of chemical precipitation were to be applied in every instance and worked with reasonable efficiency, the practical difficulty would be absolutely removed, and a steady course of improvement set in motion. If that were so, what a terrible thing it was to put upon local bodies the enormous burden of purchasing land for filtration purposes. Mr. Thomson had focussed for them the conditions which would solve the difficulty. Through this and similar societies, and by public opinion, pressure should be brought to bear upon the Joint Committee, upon the Local Government Board, and the Manchester Corporation and other local bodies to adopt the proposed solution.

Dr. D. B. HEWITT (speaking as a member of the Mersey and Irwell Joint Committee) said, that while he fully appreciated Mr. Thomson's desire to deal fairly with the question before them, he thought he had dealt rather severely with the Joint Committee, in so far that he had made a statement which he (Dr. Hewitt) would be able to show, upon authority, had no foundation whatever. He held in his hand a report presented at a recent meeting of the Joint Committee, which contained the following:—

"As there seems to be some misapprehension with regard to the principles upon which the Mersey and Irwell Joint Committee are acting and their method of applying those principles, the Sub-Committee consider it advisable to make a short statement.

"First, it is desirable to call attention to the fact that no definite standard of purity has been adopted, and the members of the Joint Committee, on reference to the proceedings, will find that so far back as December 1891, on the recommendation of Sir Henry Roscoe, a resolution was passed stating that it was undesirable to define the maximum amount of pollution to be allowed, but to insist upon the best practicable and available means being used in each case, whether a sanitary authority or a manufactory."

Therefore he took it that the Joint Committee were certainly in accord with at least one portion of Mr. Thomson's paper, but while that one sentence stood correct, there were other sentences in which he attempted to prove that a definite standard had been adopted, and it was in order that he might correct that statement that he had read the extract from the report. He had no doubt that the samples which Mr. Thomson had handed round were fair, but he (Dr. Hewitt) had seen samples laid before the Joint Committee which did not agree with the results arrived at by Mr. Thomson. He had seen hundreds of samples of sewage treated by land irrigation, precipitation, and filtration, and precipitation only, and therefore he was perfectly satisfied that it was quite possible for any local authority to produce a very good effluent by various methods of precipitation together with filtration that would not undergo secondary decomposition. The Joint Committee had, nevertheless, not yet met with an effluent that would not undergo secondary decomposition, and give off bad odours after being kept for a time. The Joint Committee were trying to induce people to adopt satisfactory methods. They had not adopted hard and fast lines. They knew there were places in the watershed producing satisfactory effluents, which if not carefully watched were apt to go wrong. With respect to Mr. Thomson's views on the purchase of land for filtration, he thought it was a great hardship that large communities should have to pay enormous prices for land under compulsion by Act of Parliament in order to protect their neighbours from river pollution. The whole object of the Joint Committee was to prevent this pollution by a similar method to that established by Dr. Angus Smith in connection with the Noxious Vapours Acts and approved by Sir Henry Roscoe. This mode of procedure was one in which the Committee had great hope for a solution of the problem. If the Corporation could make a satisfactory effluent, they could make it just as well at Davyhulme as they could at Thelwall, and if they could not, then the

natural deduction was that they wished to evade the law by the construction of a tunnel at an expenditure of 200,000. From the latest information at his disposal he did not think the Corporation intended to turn the effluent into tidal waters, but above them, in which case they would be well within the jurisdiction of the Joint Committee.

Mr. HARRY GRIMSHAW said that when the Joint Committee was first instituted and got to work, it commanded their entire approval and admiration, and it certainly raised their hopes to a very high point; but now their hopes were dashed, and he feared their chemical confidence was somewhat shaken. He was of opinion that the Committee had made the mistake of forcing people to run before they were able to walk, and before ascertaining the nature of the ground on which they were asked to walk or run. With regard to the health question, neither Mr. Thomson nor himself would attempt to argue that the pollution of streams had no effect upon health, but river pollution was not mainly responsible for a heavy death rate. In many cases, taking Manchester for instance, the idea had been exploded that the areas showing the highest death rate lay near these sewage-laden streams. The next point was that all they knew at the present time, gathered from laboratory experiments and from general observation and accumulation of facts, with regard to the condition of the sewers, tended to prove that most of the offensive odour really originated primarily in the solid matter contained in the sewage and river water; and he thought that he would not be interpreting chemical opinion wrongly if he asserted that the removal of the suspended matters would render them comparatively innocuous. Dr. Hewitt's arguments practically admitted the fact that the offence which arose from the Ship Canal could not be laid at the door of the sewage effluents which passed into it, so long as there was such a large amount of actual raw sewage from many places continually passing into the canal. He should like to suggest through Dr. Hewitt that the Joint Committee should really make a good study of what had been done in Glasgow by a system of precipitation, which appeared to produce an effluent which could not be charged with so-called secondary decomposition. There was a great danger of harassing the trades and industries of this district, of which they were the centre, and the Joint Committee could not be too careful in making progress step by step rather than endeavouring to do too much by leaps and bounds. It was said that before long the question of the Manchester sewage scheme would come before the highest court in the land. He was inclined (though it might be considered somewhat egotistical) to think that the Society of Chemical Industry was the highest court before which it could be brought.

Mr. J. CARTER BELL was surprised that Dr. Hewitt admitted that the Joint Committee had no definite standard. A number of experiments had been carried out by various companies at the Salford Sewage Works, but they could not get a definite answer from the Joint Committee as to whether the results were good enough or not. The reason why time did not answer in many cases was because sufficient was not used. Ten to fifteen grains per gallon of free lime were necessary. The drawback was the volume of sludge, and he was experimenting with another precipitant in the hope of reducing the bulk of the sludge. He preferred to use lime water, but the engineering difficulties in the way were apparently insurmountable, as they would want 200,000,000 galls. of it per day at Salford. He still had faith in lime as a good precipitant, and contended that, with a sufficient quantity in the state of lime water, he could produce an effluent that would satisfy the Ship Canal Company and the Joint Committee.

Mr. A. E. POWELL asked Dr. Hewitt if he was aware that the horrible stench about which he complained was caused by the Ship Canal Company filling the old bed of the river at Mode Wheel with the abominable sludge which they dredged from the bottom of the canal. This was worst between Salford Docks and Barton Locks, and no sanitary authority had yet interfered with them, though they had compelled corporations to adopt sanitary regulations and carry the sewage out to sea.

The CHAIRMAN said he believed the Local Government Board were mainly responsible for the present deadlock in regard to the sewage question. At the time of the Local Government Board enquiry in Manchester in 1888 it was pointed out that the area of land applied for was far too small for filtration purposes, so that the Manchester scheme ought never to have been sanctioned. The term "secondary decomposition" had been introduced in the course of the discussion, and as he had never been able to understand how this condition was usually ascertained, perhaps someone would be able to inform the meeting on this point; one thing, however, was certain—that the samples submitted by prosecutors in the law courts generally were sealed up in bottles and stank badly, while others, kept in open bottles by the defendants, were clear and sweet; and it should be remembered that the Irwell river is not covered in during its flow, but was ever free to the atmosphere. In this way he thought the prosecutions conducted on behalf of the Joint Committee were tainted a little bit too much with the desire to win their case by any means in their power. He would like to add that when the Mersey and Irwell Bill was before Parliament, a clause should have been inserted similar to that in the Alkali Act, which forbids inspectors acting as feed advisers to those they were called upon to inspect; and the sooner that some amendment of the Joint Committee's Act was made in this direction the better.

DR. HEWITT, in reply to the Chairman, assured the meeting that the greatest pressure had been brought upon the Joint Committee by manufacturers and authorities of the local districts for permission to allow their adviser to give as much information as possible; and the reason the Committee had placed the information obtained by Sir Henry Roscoe at the service of the public was simply with the view of bringing about a change for the better as soon as possible. Whatever the members of the Society might think about this, it had been done for the benefit and at the request of the public.

The CHAIRMAN: The explanation given by Dr. Hewitt might be satisfactory to the Committee themselves, but it was not satisfactory to outsiders. The alkali inspectors were often asked to give advice to manufacturers whose works they inspected, but they were not allowed to take fees for doing so.

MR. THOMSON, in reply, said he was quite aware, as Dr. Hewitt had admitted, that the Joint Committee claimed to have no definite standard, and the Rivers Pollution Act recognised no standard. At the same time, they had a working standard which had been expressly stated as equivalent to 1 grain of oxygen from permanganate per gallon and 0.1 grain of albuminoid ammonia. They did not take samples and ascertain whether they would undergo "secondary decomposition" (he should call it primary decomposition). He had seen many of Mr. Carter Bell's effluents from various processes, some of which had been corked up and others kept open, but very few of them had any objectionable smell. One third of the Manchester sewage received no treatment, and the whole of that filth was sent into the river, there to undergo decomposition. Was it not better to take all the obnoxious material from it, and, instead of trying to get certain places to produce the highest possible standard of effluent, purify the sewage by precipitation and send the sludge to sea by steamship, and then pass the effluent into the river or canal at Davyhulme? The point before the public was whether it was desirable to spend 200,000*l.* in the construction of a conduit to run this effluent to a point lower down the Canal. They were all agreed upon one point, however—that the sewage must be purified to such an extent that the effluent would not cause bad odours to be emitted from the Canal, and the question was, How could this be achieved? He was not certain that the Joint Committee would not interfere even then, as the river at Latchford was also within their jurisdiction. He had recently examined some samples of water from the River Irk, and he found some 50 grains per gallon of solid matter in suspension, whereas in cases in which he had been engaged 2 or 3 grains were considered highly objectionable. He thought it very important that the

Committee should not insist upon such high standards of purification till all the refuse waters and sewage had been treated by precipitation.

SESSION 1896-97.

Dates of Meetings.—Feb. 25th, March 25th, April 20th.

Meeting held at the Durham College of Science,  
Newcastle-on-Tyne, Thursday, December 17th, 1896.

MR. F. S. NEWALL IN THE CHAIR.

## ON SOME POINTS CONNECTED WITH TURNIP MANURING.

BY WILLIAM SOMERVILLE, D.S.C., AND R. GREIG SMITH, M.S.C.

WHEN a farmer manures his fields he expects that the most, if not all, of the costly constituents which he applies will be returned to him in the increased crop. He may manure for a particular crop or for a series of crops; in the former case artificial fertilisers are chiefly employed, and in the latter farmyard manure. Very frequently both ideas are carried out together, and dung with fertilisers is applied for the root crop, which is considered the beginning of the rotation. A root crop is necessary, in order to allow the land to be cleaned. To grow turnips well, a manure containing phosphate is required, and since this constituent can only be appropriated by plants when it is present in an easily available form, manure containing soluble or easily available phosphate must be used. It is found that increasing quantities of this manure give an increase of crop, but this increase does not correspond to the amount of manure used, and consequently a very pertinent question arises: "What becomes of the excess?" Is it taken up by the plant to produce a richer bulb? Is it in the top? Is it washed into the drains or the subsoil or does it remain in the soil? Where the excess remains in the soil it will doubtless influence the growth of the succeeding crops of the rotation, but it will gradually, as time goes on, become more and more insoluble, changing to the condition of the phosphates which occur naturally in soils. It appears to become converted into the phosphates of iron and alumina, which undergo dehydration, and become akin, so far as solubility is concerned, to crystalline or ignited phosphate, and as such it is practically lost to the farmer. Should, however, the phosphate be taken up by the plant, either in the bulbs or in the tops, it is returned to the land again as dung and as green manure, and is in this way prevented from undergoing degradation.

Of no less importance is the nitrogen, which, when applied in soluble forms, will, unless absorbed by the crop, become lost to the soil, since it is only fixed by the growing plant.

In order to throw some light upon the destination of these two constituents, their amounts were estimated in the bulbs and tops of turnips manured in different ways, during 1895. The samples were received from eight experimental stations, four of which had been manured in one way and four in

another. One set received dung along with artificial fertilisers, while the other received artificial fertilisers only.

On the field five roots were selected as average or typical specimens from each plot; these were put up into bags and, together with the tops, were sent to the laboratory of the Durham College of Science for analysis; but as the tops would have lost too much water in transit, special samples for moisture determination were taken from three stations, two of which belonged to the artificially manured series, and one to the dung set. For these samples five average tops were chosen, and each was quartered, care being taken that the dividing was uniformly done, so far as the old and the young leaves and the neck of the turnip were concerned. The quarters were put into tight tin boxes, and despatched to the laboratory, where they were cut up and tested for moisture. The turnips, on arrival, were washed and dried, the tops and tails pared, and the bulbs cut into vertical segments like orange ribs. One segment from each turnip was many times cut transversely, by means of a machine bread knife, to within an eighth of an inch of one of the vertical sides, a proceeding which caused the portion, as it dried, to spread out fanwise, and so expose a maximum amount of surface. These were threaded upon thin wire, and hung over tin boxes similar to those used for baking bread. The samples were at first dried slowly in the air, then, after a time, were put into a warm cupboard, and when all danger of "stewing" was past, they were dried in the steam-bath until they became sufficiently brittle to grind. For the moisture determinations, tapering wedge-shaped portions were cut from the centre of a section of each root. These were sliced, after the manner of the larger portions, weighed, and dried, at first slowly, then for 24 hours at 103° C. In the powdered portions of the large samples, the moisture was estimated by exposure to 100° C. in the air-bath for three hours.

The well-known Kjeldahl method was used for the estimation of the nitrogen, and the phosphoric acid was determined in the ash by precipitation with magnesium chloride in the presence of citrate and ammonia. In the case of the tops, the silica was eliminated previous to precipitation, but this preparation was unnecessary with the roots.

The greatest care was observed that every determination of each constituent was performed in precisely the same way, so that the results could be compared one with the other.

In the set getting artificial manure, swedes were sent from two of the farms and yellow turnips from the others; with the lot receiving dung and artificial fertilisers, three farms sent swedes and one yellows. The names of the farmers and the kind of turnip grown in each trial are given below. Further detail as to the trials will be found in the *Fourth Annual Report on Manurial Trials (Dr. Somerville), Season 1895*.

#### Manuring with Artificial Fertilisers alone.

It is noticed that when turnips are grown upon unmanured soil, the individual bulbs are smaller than those raised under more favourable circumstances, and as a con-

sequence the yield is also smaller. The smaller roots are, however, firmer, and one is led to expect that this firmness means less water—that is more solids—an expectation which is realised by the percentage of solid matter in the bulbs of plot 1, being higher than in any other plot.

The addition of phosphoric acid and potash, however, or these with a small quantity ( $\frac{1}{2}$  cwt.) of nitrate of soda, does not materially alter the amount of solids in the roots; but from the diminution in the tops, as will be emphasized later, mineral manures alone, or with the addition of small quantities of nitrate, appear to make the plants mature earlier.

As the nitrate is gradually increased no regular variation in the bulbs is obtained, those receiving the medium application (1 cwt.) have least dry matter. On the other hand, the tops show a steady decrease in solids with increase of nitrate of soda in the manure. This, however, only holds good to a certain extent. Very soon a limit is reached, and we see from plot 8, receiving 2 cwt. of nitrate, the solids in the tops are greater than on plot 7, getting  $1\frac{1}{2}$  cwt. The nitrate on both these plots was applied at the same time, *viz.*, half with the seed and half at thinning.

As the application of nitrate is delayed, the period of growth is prolonged, a state of things indicated, not only by the luxuriant appearance of the tops when the turnips were lifted, but also by the analysis. Plots 5, 7, and 6 each received a phospho-potassic manure with  $1\frac{1}{2}$  cwt. of nitrate of soda, the latter being sown with the seed on plot 5, spread broadcast at sowing time on plot 6, while on plot 7 it was applied half the one way and half the other. The later sowing has produced a less percentage of solids in the bulbs and a greater percentage in the tops than the earlier, while the half-and-half mode of application of plot 7 lies between the two. Evidently the leaf cells of the plants are actively manufacturing organic matter, and as the plant matures, or as the stimulating effect of the nitrate declines, the percentage of solids in the leaf falls whilst that of the bulb increases.

The action of phosphoric acid in forcing the crop is shown by plot 10, which received dissolved bones in addition to nitrate, kainit, and superphosphate. There is about as much total nitrogen in this manuring as in the case of plot 4, so that these two may be compared and the action of the extra phosphate observed, but a general survey of all the analyses shows that in the dissolved bone plot the solids of the bulbs are at a maximum and of the tops at a minimum, which can only be accounted for by the extra phosphate.

Potash appears to be necessary for quick ripening, and in this respect plays much the same part as phosphoric acid. The incomplete manure (plot 9) has less solids in the bulbs and more in the tops than plot 10; evidently the lack of potash causes the solids to remain largely in the tops when the crop is pulled.

It is a general rule that when any single manurial constituent is sown, the amount in the crop is increased; and phosphate shows itself to be no exception, as both bulbs and tops hold increased percentages of phosphoric acid through the action of the superphosphate. The absence of nitrogen in the manure of plot 2 has been reflected in the contents of the bulbs. Most of the plots in this experiment have had the same quantity of minerals, with varying amounts of nitrate, or with the same quantity of nitrate applied at different times, and on that account it is with the nitrogen that differences are to be expected.

Nitrate in small quantity, *viz.*,  $\frac{1}{2}$  cwt. per acre, does not alter the quantity of nitrogen in the bulb, but when given in larger doses, a considerable increase in nitrogen is obtained. Speaking broadly, there does not appear to be a constant rise in percentage of nitrogen with a continual increase of nitrogenous manure; either nothing happens, or the percentage is raised to what may be considered the normal amount, since it is the same as is found in the unmanured crop. But a closer examination of the figures shows that the percentage varies slightly with the manure, there being a rise in the case of the bulb nitrogen and a

\*Tops from these farms were examined for moisture. Another set of samples of tops was received from Mr. R. H. Cleashy, Broom-side, Durham, on whose farm an experiment of the artificial fertiliser set was carried out, and moisture averages were struck between these and the tops from Mr. J. T. Armstrong.

constant fall with the nitrogen of the tops, from which it would appear that the more nitrate we apply at one time, the greater is the percentage of nitrogen found in the bulbs and the less in the leaves. This, however, only holds good to a limit expressed by the ratio of 5 cwt. of superphosphate to 1½ cwt. of nitrate of soda, for when the last manure is raised beyond this, as shown by plots 7 and 8, the bulb nitrogen is constant, while the top nitrogen is increased. The phosphoric acid is constant when the same weight of superphosphate is applied and when the nitrate is all put on at the same time, but when put on at different times

more is found in the tops and less in the bulbs with the later manurings.

Dissolved bones have had practically no effect upon the phosphoric acid, probably because the plant has had as much as it required in the superphosphate; but the nitrogen has been raised in the bulbs and lowered in the tops, as is seen on comparing plot 10 with plot 3, both of which received the same amount of nitrate of soda.

Potash decreases the phosphoric acid all over the plant; and its action is very marked on the nitrogen, that in the bulb being increased and that in the top decreased.

\* Nitrate all applied before sowing.

† Nitrate all applied after thinning.

‡ Nitrate applied half before sowing and half after thinning.

The amount of solid matter produced per acre in the bulbs should be of more importance than the weight of crop, since turnips are grown primarily for food. Closely connected with the question of quantity is that of quality, which is indicated by the nitrogen contained in the solids. Looking over Table II. we see that the roots receiving superphosphate, kainit, and 1½ cwt. of nitrate of soda contain most solids, and further, that, with this group, the best result is obtained when the nitrate has been all applied at sowing. With the early application of 1½ cwt. of nitrate, the plants are given a start which enables them to keep well ahead of those receiving less manure, or the same quantity applied at later periods. What the later sowings want in root solids they make up for in top solids, and as a consequence the total organic matter per acre is practically the same in all three cases.

The effect of the time of application is shown better here than in the total crop, which shows a difference of 4 cwt. of roots to the credit of the intermediate application, while

the solids are actually lower by 55 lb. Assuming these roots to contain an average of 9 per cent. of solids, the 55 lb. of dry matter would be equivalent to 5½ cwt.; so that, while the weight of crop per acre of the roots receiving the nitrate half at sowing and half at singling is 4 cwt. more than when the nitrate is applied all at sowing, in reality, so far as the solids are concerned, the bulbs are 5½ cwt. less.

An increase of nitrate over the 1½ cwt. has depressed the solids very considerably. As a rule an increase of nitrate produces an increase of crop,\* but with the four stations of the set the crops have been in three cases much diminished: with the diminution in the crop there has been no corresponding rise in the percentage of solids, and we are therefore compelled to conclude that with the applied amounts of superphosphate and kainit, 1½ cwt. of nitrate of soda is the optimum quantity.

Just as 2 cwt. show over-maturing, quantities less than  $1\frac{1}{2}$  cwt. show under-maturing, and so long as the manure contains an insufficiency of nitrate it does not appear to matter much whether a whole or a half cwt. is applied. Again, this is at variance with conclusions regarding the action of nitrate based upon the weight of crop.

It would seem that the ratio of nitrogen to phosphate in a turnip manure should be as 1:  $5\frac{1}{2}$ , or one part of ammonia to five of phosphate when the manure contains potash and when no dung is applied.

Increasing the amount of phosphate by means of dissolved bones, which contributes combined phosphoric acid and nitrogen in many different conditions as regards solubility and availability, has increased the solids (compare

plot 4), but perhaps its best point is that the extra phosphate has caused an earlier ripening.

When no farmyard manure is applied to the turnip break, potash should on no account be omitted, as has been demonstrated in the North of England field trials.\* Theoretically potash is more important than phosphoric acid as a manurial constituent for the crop; but practically, owing to the turnip's facility for taking up this constituent from the soil, potash becomes of relatively less importance; still it should not be ignored if a good crop of bulbs is desired. A comparison of plots 9 and 10 shows that through the action of the kainit about 300 lb. of solid matter have been transferred from the top to the root.

§ Soluble phosphoric acid only of superphosphate taken.

#### The Destination of the Phosphate and the Nitrogen.

Having considered the solids, the nitrogen, and the phosphoric acid, there remains the very important question of the amount of the last two constituents abstracted by the plant from the soil. From this the quantity of manure remaining in the soil can be calculated. To effect this, the number of pounds per acre of the constituents in root and top are added together and, in the case of phosphoric acid, subtracted from the amount in plot 1; in the case of nitrogen, subtracted from that in plot 2. The unmanured plot must be credited with having taken up all the available phosphate. The plots manured with nitrate received also superphosphate and kainit, both of which have, as may be seen by comparing plots 1 and 2, enabled the plant to take up more nitrogen from the soil. That this could be done infers that in the unmanured plot the soil nitrogen was not deficient, and there was enough for the available phosphate. In the phosphoric acid question, therefore, the subtraction of plot 1 from the others is justified. A glance at the table shows that only about a quarter of the phosphate applied in the manure has been taken up by the crop; the rest remains in the soil. The nitrogen varies considerably according to the amount used and the time of application. In some cases what is applied is not abstracted by the crop, and in others there is much more. It will, however, be better to discuss these results in detail.

In the plots 2 up to 8, each received 5 cwt. of superphosphate containing 75.2 lb. of soluble phosphoric acid, while plots 9 and 10 got the same quantity of superphosphate, together with 2½ cwt. of dissolved bones, in all 121.8 lb. of phosphoric acid. Without nitrate, 14.6 lb. are absorbed by the plant from the manure, and 60.6 lb. remain in the soil, part of which will benefit the next and a few succeeding crops, while the rest will become, as shown in the Rothamsted experiments, an integral portion of the soil and will be taken up with extreme slowness.

With the application of  $\frac{1}{2}$  cwt. of nitrate, rather more (0.8 lb.) is left behind, but with the nitrate still increasing; less and less phosphoric acid remains in the soil. This is in all probability due to the nitrate increasing the crop, and with it the root fibres, which ramify throughout the soil and absorb the manure from the phosphate-coated particles. As the manuring with nitrate is deferred, more phosphate is taken up, since plots 5 and 7 are very similar and plot 6 much greater. Increasing the quantity of nitrate over  $1\frac{1}{2}$  cwt. rather prevents the assimilation of the phosphate. Dissolved bones have left all their phosphoric acid in the soil, and kainit has caused the crop to leave more than would have been the case had the manure been withheld.

On the whole, the phosphoric acid story is a very sad one: so much must be applied to grow a respectable crop, and at the same time the most of it is left in the soil to become so insoluble that succeeding crops can only take it up with difficulty. This, however, is precisely what has been found to be the case by the Rothamsted and other experimenters.

The nitrogen question is more interesting. As shown in the column "Roots and Tops, less plot 2," the application of  $1\frac{1}{2}$  cwt. of nitrate of soda has resulted in least loss. Of all the manurial constituents, nitrogen is the one which we desire to have in the crop; for, should it be left in the soil, excepting as root residue, we do not expect to find it there in the succeeding season.

Plots 3, 4, and 5 show that as the application of nitrate increases, the quantity left in the soil gets less and less. With  $1\frac{1}{2}$  cwt., the quantity left in the soil is practically nil; and when we consider that this plot grew the largest crop, we must conclude that the nitrate has been all saved, for much more than 0.7 lb. would be found in the root residue.

\* Manurial Trials, season, 1895, page 73.

As the time of manuring is deferred, the nitrogen abstracted and found in the crop increases to such an extent that there is a very material gain of this constituent.

Plot.	Minerals with 1½ cwt. Nitrate of Soda.	Nitrogen.
5	Applied at sowing.....	0.7 lb. left in soil.
7	Applied half at sowing, half at thinning.	10.3 lb. excess in plant.
6	Applied at thinning.....	10.6 lb. " "

From loss that must occur through drainage, one expects that a considerable portion of the nitrate applied in the early season will be lost to the soil and to the crop; but these results show a very small loss under conditions of rational manuring, that is to say, with a perfectly balanced manure. At first sight, the increase of nitrogen would seem to indicate what is not justified by our present knowledge, *viz.*, a fixation of nitrogen by the turnip crop; but it must be remembered that in all probability the nitrogen in the crop of plot 2, which we have assumed to be the soil nitrogen which has nitrified and been absorbed by the plant, is in reality only a portion of it, the rest having been lost by drainage. This loss is the less the greater the crop, and with the heavier and later doses of nitrate the loss has been minimised to such an extent as to appear a gain. Moreover, the later application of nitrate occurs at a time when the plant is in a more forward state; it is growing more freely, and is more capable of absorbing the manure. The crops of plots 6 and 7 were lifted along with the others at a time which, though correct for the plots as a whole, would have been too early for these two taken individually. They have evidently not reached maturity, and with a mild season they would have continued to grow and mature, with the result that the excess of nitrogen which is in the tops would in all probability have been transferred to the bulbs with undoubted advantage.

The application of 2 cwt. of nitrate has evidently disturbed the balance of the manorial constituents, and what was a gain (plot 7) has become an evident loss.

Kainit produced a material increase in the crop and in the solids, but it has practically no effect on the phosphates and the nitrogen withdrawn from the soil. The dissolved bone plot produced about the same crop as plot 4, both of which were manured with about the same quantity of nitrogen; it produced 12½ cwt. of roots more than plot 3, but has abstracted a little less phosphate and a little more nitrogen from the soil. All the phosphate and two-thirds of the nitrogen of the bones have practically been left in the soil.

#### Manuring with Dung and Artificial Fertilisers.

It is the usual agricultural custom to spread farmyard manure either over the stubble or along the drills previous to sowing the turnip seed, and most farmers declare that it is impossible to grow a crop of swedes—that is, a good one—without dung; consequently a “mucking” forms an essential feature of turnip manuring. On this account any information regarding the constituents taken up by the root crop manured in the customary way should be of some value. At the outset, however, the variable nature of farmyard manure must be considered. It is always applied in cartloads, the contents of which may weigh 12, 14, 16, or even 20 cwt. As a rule they are assumed to be 16 cwt. In composition, this natural manure is most variable, and depends upon a number of factors, such as the “ripeness” of the heap, the feeding of the stock, the kind of animal producing it, the method of storage and treatment, the kind and amount of litter used, and so on. Lawes and Gilbert, recognising the difficulty, not only of sampling the manure, but also of pitching upon any one heap as being typical, preferred to calculate rather than analyse its composition. Their result agrees closely with that obtained by the late Dr. Voeleker from manure sampled with the greatest care. The tabulated percentages of water-

soluble and insoluble nitrogen and phosphoric acid are taken from Dr. Voeleker's figures, and the amounts in 16 loads are from them calculated. The nitrogen soluble in water,

Phosphoric acid	0.175	0.274	50	78

and on that account readily available as plant food, is about equal to that contained in a little over 5 cwt. of nitrate of soda, while the soluble phosphoric acid in the 16 loads and in 3½ cwt. of superphosphate is about the same. The insoluble nitrogen and phosphoric acid will probably not contribute much towards the crop to which they are applied. A farmer would never think of manuring his turnips with these quantities of artificials, and yet long practice and experience has shown him that 16 loads of dung is only a medium dressing.

The scheme of the experiment, consisting of dung with different amounts of artificial fertilisers, may be gathered from Table IV.

The effect of dung alone, as seen by comparing plots 2 and 1, has shown itself chiefly in the production of solids, which are materially increased so far as percentage is concerned and nearly doubled in amount. An increase in the nitrogen content of the roots and tops ought to be expected from the quantity of this constituent in the dung, but the two plots give the same analysis showing that the manure has directed itself to increasing the crop and not to improving the quality. The phosphoric acid, however, is decidedly increased not only in the bulbs but also in the tops, a circumstance which probably indicates a more mature crop, and this opinion is endorsed by the lower ratio of the top solids to the roots.

The addition of varying amounts of nitrate tells practically nothing beyond the fact that 1 cwt. to 16 loads of dung has done least harm; the single cwt. has given a greater percentage and amount of solids than the lower and the higher quantity.

Manuring with increasing quantities of superphosphate causes a rise in the figures all round; the phosphoric acid, the nitrogen, and the solids both in bulb and top, and the amount of solids per acre gradually increase with the manure. One is prepared to expect good things of phosphate since the dung is so essentially nitrogenous and the regularity of increase in the percentages confirms the belief that there is enough nitrogen in the dung for almost any quantity of superphosphate and certainly for 7½ cwt. The ratio of tops to roots is very small, the energies of the plant under the action of the added fertilisers being apparently devoted to forming the bulb.

Kainit and dung together have a very disastrous effect; the percentage of solids and of nitrogen are much decreased. Potash has had no influence upon the phosphoric acid of the roots nor on the composition of the tops, but it has prevented, as shown by the lessened ratio, that luxuriant growth of leaf so characteristic of nitrogen. The weight of roots grown per acre was not increased by the potash, and since they were much more watery than those grown with dung alone, the solids came out much less.

Dissolved bones and kainit have done exceedingly well, especially with the smaller quantity of the former manure. The bulb constituents are high, and there are more solids than in any other plot. Doubling the quantity of the bones has not altered the per cent. of nitrogen, but has decreased the phosphoric acid in the bulbs, and has increased that in the tops.

Bone-meal has practically been inoperative and bears out what is generally shown in field experiments, that it is decomposed in the soil with exceeding slowness. Along

with dung it should be seen to best advantage, because the liquid of the manure would supply a capital medium for fostering the bacteria which change the organic matter of the bone into simpler bodies. Undoubtedly some phosphate has been dissolved, and as a result the solid matter per acre has been increased.

The addition of the complex manure has brought about no great change. The solids are lessened, though by increasing the crop the total solids per acre have benefited, and since the root composition is unaltered and the ratio diminished, one may be justified in concluding that the period of growth has been shortened.

\* Soluble phosphoric acid only of superphosphate taken.

### The Destination of the Phosphate and the Nitrogen.

What strikes one most on looking over Table VI. is the general uselessness of attempting to assist the action of dung as a manure for turnips. So far as the solids are concerned, only 6 out of 11 plots give an excess over the farmyard-manure plot, and these same plots take more phosphoric acid out of the soil, four of these and another give more nitrogen in the total plant, but only three contribute more nitrogen in the bulbs.

The total crop of plot 2 has taken from the dung about half of the soluble nitrogen and phosphoric acid, about one quarter of the total nitrogen, and one-fifth of the total phosphoric acid.

Increasing quantities of nitrate of soda do not cause proportionate amounts of nitrogen to be taken up. The medium quantity has taken out least not only in bulbs but also in tops. That with 1½ cwt. is the only one of the nitrate plots that contains more nitrogen than the dung plot, and the excess (about one-fifteenth of that applied in the manure) is not in the bulbs but in the tops. The object of adding nitrate to dung would be, if anything, to increase the nitrogen of the crop, and especially of the bulbs, a thing which it has signally failed to do, consequently we must look upon the nitrate applied with dung as remaining in the soil, and therefore being practically lost.

Adding increasing doses of phosphate, regularly, augments the crop, and causes the plant as a whole to take up proportionate amounts of this constituent. The smallest quantity is lost, for although the bulbs are richer than those on plot 2, the tops are poorer, and as a net result, there is less phosphoric acid recovered. With the double and treble quantities, about an eleventh of the acid is returned in the crop. Though the recovery of nitrogen is proportional to the phosphoric acid, in no case does it exceed that of the plot manured with dung alone.

When kainit was added to the farmyard manure, it had very little effect upon the amount of crop, and it has shown itself to be markedly detrimental to the assimilation of nitrogen, and, to a less degree, the phosphoric acid.

Questions of loss are always very depressing, and accordingly it is a pleasure to consider the action of dissolved bones with kainit, which together form a capital manure. With this combination there is virtually a gain all round. The larger quantity has been less successful than the smaller, in which from a fourth to a fifth of the phosphate has been recovered. Why the larger quantity of manure has failed while the smaller has succeeded is a matter of conjecture, and with our present knowledge it would be perhaps unwise to hazard any speculation, except the very broad one that, given certain climatic conditions there is a definite proportion between the food constituent which contribute to the nourishment of particular crops, and this ratio is disturbed with detriment to the plant.

Bone meal has returned a little of its nitrogen and phosphoric acid in the tops, the roots are practically unaffected.

The mixed manure has comparatively speaking done exceedingly well, a tenth of the phosphate applied is nearly all in the bulb, and though more nitrogen has been recovered by some of the other plots, yet the albuminoids of the bulbs are second to none.

On the whole, the addition of the one-sided artificial fertilisers to the multiform farmyard manure has resulted in a loss, nitrate and potash causing a loss of both constituents and phosphate a loss of nitrogen. It is only when a general manure, such as the mixed fertilisers or as kainit with dissolved bones, which contains various forms of phosphate and combined nitrogen, is used, that some of all the constituents are recovered in the crop.

#### SESSION 1896-97.

Dates of Meetings.—Feb. 24th (Nottingham), March 24th (Nottingham), April 28th (Derby), May 26th (Nottingham).

Meeting held in Derby, Wednesday, December 16th, 1896.

MR. F. J. R. CARULLA IN THE CHAIR.

### THE FILTRATION OF SEWAGE THROUGH COKE BREEZE.

BY S. F. BURFORD, F.C.S., AND THOS. READER SMITH, ASSOC. M. INST. C.E.

THE use of coke as a filtering medium for sewage effluents, though often tried, has not hitherto proved sufficiently effective to be generally adopted. This may have arisen from the fact that the filters have frequently been too small, whilst the pieces of coke have been too large, leaving considerable spaces between, and also that the rate of passage through the filters has been too rapid, so that the so-called filters have simply acted as screens or strainers.

The results obtained by Mr. Dibdin in his experiments on London sewage, in which coke-breeze was employed, but with important modifications of the usual method, have attracted considerable attention.

The following is a record of work with an experimental filter at the Kettering Sewage Disposal Works, on the lines recommended by Mr. Dibdin. The sewage is that of a manufacturing town in which leather works constitute the chief industry; there are also dyeworks and tanneries. The water supply is less than 20 galls. per head, and a portion of the storm water is diverted.

It will be seen that the crude sewage is very foul, it is fairly represented by the sample below.

	Ammonia.		Oxygen consumed at 80° F.	
	Chlorine.		In 15 M.	In 4 Hours.
	Free.	Albumenoid.		
Grains per gallon.	10.29	7.945	2.205	4.6061 5.5416

On arrival at the works the sewage is treated with lime and sulphate of alumina, in the form of aluminoferric, in the proportion of 7.8 grains of lime per gallon, and 4.7 grains per gallon of aluminoferric, reckoned on an average daily flow of 500,000 gallons. The sewage, after treatment, flows continuously through the precipitation tanks.

The filter measures 21 ft. by 10 ft. by 3 ft. deep; there are 2-in. drain pipes at the bottom; it is filled to a depth of 2 ft. 9 ins. with small coke, the size of walnut, and covered at the top with 3 ins. of gravel. The discharge is controlled by a valve. Reckoning the water space as half the total contents of the filters it would contain about 2,000 gallons of effluent.

The experiment was commenced on the 26th Feb. 1896 by charging the filter with tank effluent, after precipitation with lime and aluminoferric. The process of filling occupied 30 minutes, and portions were taken every five minutes and mixed for analysis. The filter was left at rest for one hour and then slowly emptied during two hours; portions being taken every 15 minutes and mixed for analysis. It

was worked in this way once a day, Sundays excepted, up to the 19th of March, being filled between noon and 1 p.m.

Samples were taken daily for the first five days, and afterwards on Tuesdays and Thursdays, as being representative days.

The following are the analyses for this period, all parts being expressed in grains per gallon:—

From March 24 to April 23 the experiment was varied, an earlier sewage, 10.30—11.0 a.m., being used, and the tank effluent allowed to remain at rest in the filter for

3 hours. After April 1, carbferalum, 3.13 grains per gall. was substituted for the aluminoferric.

The analyses for this period are as follows:—

Tank Effluents.						Filter Effluents.						Nitrogen as Nitrates.

From May 22 the filter was worked twice daily, being filled from 10.30 to 11 a.m., and from 6.0 to 6.30 p.m., and left at rest for three hours each time.

After June 2 the amount of carbiferalum was increased to 4.7 grains per gallon.

During the entire course of these experiments there was never any indication of putridity, and when the experiments were stopped on June 16th, and the filter broken into, the cake was found to be absolutely free from any putrid odour. In all cases the filter effluent was clear and comparatively free from odour.

The results of these experiments indicate that the process is worthy of trial on a larger scale, and that if the filter be carefully constructed, the effluent allowed to remain at rest for some hours, and thorough aeration induced, the process is a valuable help in the treatment of sewage effluent.

Further experiments will be made as steps are being taken to construct large filters.

It will be noticed that in Mr. Dibdin's experiments the degree of purification, whether judged by ammonias or oxygen consumed was about the same, being 75 to 80 per cent. as compared with the unfiltered effluent. In our experiments the purification was not so considerable, and as judged by the oxygen consumed was much higher than in the case of the ammonias, this probably arising from the different character of the crude sewage.

## DISCUSSION.

Mr. JNO. WHITE (County Analyst, Derbyshire) said that he was impressed with the very irregular manner in which the improvement was brought about. If they took the tank effluent of April 7th and looked at the amount of albuminoid ammonia, 0.476, they would see that it had increased to 0.483 on the same day in the filter effluent, while if they referred to the next sample, two days later, they found a reduction from 0.609 to 0.483. There were very many striking examples of that kind to be found, but the figures wanted careful study.

Mr. F. E. LOTT said that five or six years ago he had, in conjunction with his partner Mr. Matthews, carried out several experiments upon a pretty bad sewage, both with and without chemicals, and they noted one point which, as far as they then knew, was not previously commented on, namely, that the amount of deposit, when sewage was allowed to settle without any chemical treatment at all, was very considerable; and when treated with the small amount of chemicals frequently recommended, the result hardly supported the strong claim in favour of such treatment, that was to say, simply as regarded precipitation. In respect to the actual precipitation effect of chemicals upon sewage, there was a great divergence of opinion in the various papers read on this subject. In an experiment lasting four or five days they found that a million gallons of sewage passing slowly through the experimental tanks deposited 8.8 tons of sludge by simple subsidence, whereas treated with 10 grains of lime per gallon a similar quantity of sewage yielded only 15.7 tons of sludge—a considerable increase, but not so great when the actual amount of lime added and precipitated is deducted—a point they particularly noted was that when air-drying the sludge, that obtained by simple subsidence was much less offensive than that obtained by precipitation with lime or with other chemicals tried. He would like the opinion of the authors of this paper upon the question of precipitation apart from

the chemical changes. He would further like to ask if the sewage they experimented with was allowed to partially settle before treatment. That, he thought, was an important point, as his opinion was that sewage allowed to settle in tanks before the addition of chemicals gave much better results when subsequently treated than when the chemicals were added originally to the raw sewage. There were chemicals which assisted as separators of suspended and other matter, and chemicals which only made the effluent less offensive; fortunately the two sets of chemicals were not always identical, and might therefore be used at different times.

Mr. J. T. WOOD said Mr. Reader Smith had told them that the sewage of the town of Kettering was to a large extent from tannery and leather works, and it was a well-known fact that sewage from places of that character containing lime liquors and waste tan liquors mutually precipitated one another. Tanneries dealing with their own sewage could very often get a clear effluent without any other treatment than simply mixing the different liquors in the works. It was known in bacteriological work that small quantities of antiseptics seemed to have a vivifying effect on many micro-organisms. Very small quantities actually seemed to increase the activity of the bacteria. It occurred to him that the same was the case with lime, though it may have increased the putrefaction going on in the sewage merely by rendering it alkaline.

Mr. L. ARCHBUTT said that there were several figures he found it difficult to reconcile with each other. Take, for instance, the sewage on April 7th. They found free ammonia 2.352, and in the filter effluent 1.848—a decrease of half a grain per gallon. There was a slight increase in the albuminoid ammonia, and an increase in the nitrogen as nitrates of 0.912 grain. But on April 9th, two days later, they found a decrease in the free ammonia of 1.12 grains, a decrease also in the albuminoid ammonia of 0.226 grain, and yet the nitrates only showed an increase of 0.48 grain. On May 7th, there was a still more extraordinary result, the free ammonia disappearing to the extent of 1.14 grains per gallon, the albuminoid ammonia 0.322 grain, and yet the nitrates had, according to the analyses, diminished also from 0.288 to 0.128 grain. These figures, to his mind, appeared to indicate that putrefaction was going on, but he would be glad to hear what explanation the readers of the paper had to offer.

Mr. S. F. BERFORD, in reply, said certain variations and irregularities were due to the fact that one day the sewage would be in its normal state and then the next it would be abnormal. With regard to the matter of the amount of lime to be used, it would first be necessary to ascertain the nature of the sewage.

Mr. T. READER SMITH also replied, and said he found that a much clearer effluent could be got by the use of chemicals than without, and they also got a much more rapid precipitation. With reference to the amount of sludge precipitated, they had had 80 tons per day, representing 8 tons of pressed cake.

The CHAIRMAN said the sewage question was one of the greatest importance to them in Derby. He was only sorry that they had not had any Town Councillors there

that evening, as they might have asked some questions to elucidate the points in dispute between the town and county.

### SOME PROPERTIES OF CERTAIN METALLIC PHOSPHATES.

BY R. M. CAVEN B.Sc., F.I.C., AND A. HILL.

IN extension of the observations made by one of us on some properties of ferric phosphate (this Journal, January 31st, 1896), we have made experiments on the hydrolysis of the phosphates of certain other metals, by water and aqueous potash and ammonia. It has already been shown that  $\text{FePO}_4$  is completely hydrolysed by  $\text{NH}_4\text{HO}$  aq. and therefore, *a fortiori* by  $\text{KHO}$  solution. Experiments were next made on *aluminium phosphate*; and since this compound is readily soluble in  $\text{KHO}$  aq. and  $\text{NH}_4\text{HO}$  aq., behaviour analogous to that of  $\text{FePO}_4$  with these reagents could not be looked for. On account of this fact the precipitation of  $\text{Al}(\text{OH})_3$  by the decomposition of  $\text{AlPO}_4$  in presence of excess of  $\text{KHO}$  aq. or  $\text{NH}_4\text{HO}$  aq., could not be achieved, nor the hydrolysis demonstrated.

It is well known that  $\text{AlPO}_4$  is soluble in solutions of  $\text{Al}$  salts. If  $\text{Na}_2\text{HPO}_4$  aq. is added drop by drop to a solution of pure  $\text{Al}_2(\text{SO}_4)_3$  in water, at first no precipitate appears, and then a cloudiness which disappears on shaking. When as much  $\text{Na}_2\text{HPO}_4$  aq. has been added as the clear solution can contain, slight warming causes a cloudiness, and, on boiling the liquid,  $\text{AlPO}_4$  is gradually reprecipitated, but upwards of an hour's boiling is necessary for complete precipitation. The clear filtrate is then found to contain both  $\text{Al}$  and  $\text{PO}_4$ ; so that  $\text{AlPO}_4$  is somewhat soluble in  $\text{Al}_2(\text{SO}_4)_3$  aq., even at the boiling point of the latter. Slight precipitation of  $\text{AlPO}_4$  from its saturated solution obtained by shaking with  $\text{Al}_2(\text{SO}_4)_3$  aq. occurs, on standing, even in the cold. The addition of  $\text{NH}_4\text{Cl}$  aq. to this solution does not cause any precipitation.

If  $\text{AlPO}_4$  is dissolved in  $\text{NH}_4\text{HO}$  aq.,  $\text{KHO}$  aq., or  $\text{NaHO}$  aq., it is partially reprecipitated from these solutions by the addition of  $\text{NH}_4\text{Cl}$  aq.; the completeness of the reprecipitation depending on the relative masses of chloride and hydroxide present.  $\text{NH}_4\text{HO}$  aq. added after some  $\text{NH}_4\text{Cl}$  aq. to  $\text{AlPO}_4$  dissolved some of the precipitate, and the  $\text{AlPO}_4$  was again precipitated from solution on adding more  $\text{NH}_4\text{Cl}$  aq. to the filtrate.

$\text{AlPO}_4$  is soluble in a large quantity of  $\text{H}_2\text{A}$  aq. in the cold, and is reprecipitated from this solution on boiling, but not by  $\text{NH}_4\text{A}$  aq. in the cold. If some  $\text{AlPO}_4$  is dissolved in the least possible quantity of  $\text{HCl}$  aq.,  $\text{H}_2\text{A}$  aq. added in excess and then  $\text{NH}_4\text{A}$  aq., no precipitation takes place. If only a few drops of  $\text{H}_2\text{A}$  aq. have been added,  $\text{AlPO}_4$  comes down on the addition of  $\text{NH}_4\text{A}$  aq., but this precipitate is redissolved completely on the addition of excess of  $\text{H}_2\text{A}$  aq. A solution of  $\text{Al}_2(\text{SO}_4)_3$  containing a little  $\text{AlPO}_4$  was not precipitated by  $\text{H}_2\text{A}$  aq. and  $\text{NH}_4\text{A}$  aq., but the addition of a little  $\text{Na}_2\text{HPO}_4$  aq. caused precipitation. Also a solution of  $\text{AlPO}_4$  in  $\text{Al}_2(\text{SO}_4)_3$  aq., containing almost a saturating amount of  $\text{AlPO}_4$  yielded a precipitate with  $\text{H}_2\text{A}$  aq. and  $\text{NH}_4\text{A}$  aq.

The slow hydrolysis of  $\text{AlPO}_4$  by water (as well as that of  $\text{FePO}_4$ ) was shown by R. T. Thomson (this Journal, March 29, 1886).

The properties of *chromic phosphate* are very similar to those of  $\text{AlPO}_4$ .  $\text{CrPO}_4$  was found to be soluble in  $\text{Cr}_2(\text{SO}_4)_3$  aq. though not to such an extent as in the case of  $\text{AlPO}_4$  in  $\text{Al}_2(\text{SO}_4)_3$  aq.

When a saturated solution was made by adding  $\text{Na}_2\text{HPO}_4$  aq. to  $\text{Cr}_2(\text{SO}_4)_3$  aq., until a permanent precipitate remained after shaking, the clear filtrate deposited  $\text{CrPO}_4$  on being warmed. The complete precipitation was less tedious than in the case of the solution of  $\text{AlPO}_4$  in  $\text{Al}_2(\text{SO}_4)_3$  aq., but, after boiling produced no further turbidity, the clear liquid was found to contain  $\text{PO}_4$ .  $\text{NH}_4\text{Cl}$  aq. did not cause the saturated solution to precipitate.

$\text{CrPO}_4$  is soluble in a moderate quantity of  $\text{NH}_4\text{HO}$  aq. in the cold, though much less readily soluble than  $\text{AlPO}_4$ . A reddish-violet liquid is formed, from which the addition

of  $\text{NH}_4\text{Cl}$  aq. causes a partial reprecipitation of  $\text{CrPO}_4$ .  $\text{CrPO}_4$  is also precipitated from its solution in  $\text{KOH}$  aq. by a moderate quantity of  $\text{NH}_4\text{Cl}$  aq., as is the case with  $\text{AlPO}_4$ .

$\text{CrPO}_4$  is readily soluble in  $\text{H}_2\text{A}$  aq., and when this reagent is added in moderate quantity after the precipitation of  $\text{CrPO}_4$  from a nearly neutral solution by  $\text{NH}_4\text{A}$  aq., it redissolves much, or even all, of the precipitate.

Hot water hydrolyses  $\text{CrPO}_4$ . The precipitate obtained by adding  $\text{Na}_2\text{HPO}_4$  aq. to  $\text{Cr}_2(\text{SO}_4)_3$  aq. was washed with repeated quantities of hot water, and after all the sulphate had been washed away, much  $\text{PO}_4$  appeared in each lot of wash water. The precipitate, which settled with difficulty at first, became much denser during the process of washing, and then settled quickly. The colour of the precipitate also changed from greyish-green to dark green.

For the detection of  $\text{Fe}$ ,  $\text{Al}$ , and  $\text{Cr}$ , in a mixed precipitate of their phosphates, the following method has proved very satisfactory. Dry the precipitate and heat it in a Pt. box—made by folding a piece of foil 2 ins. square over a block  $1\frac{1}{2}$  ins. square—together with enough solid  $\text{KHO}$ , free from  $\text{Al}$ , to enable the whole to fuse together.

Maintain the mass in a state of fusion over the Bunsen flame, and freely exposed to the air for a minute or two, and when cold extract with water and filter. The  $\text{Fe}$  will be present as  $\text{Fe}_2\text{O}_3$ , which will remain on the filter, and the  $\text{Al}$  and  $\text{Cr}$  will be in the alkaline filtrate. The addition of excess of  $\text{NH}_4\text{Cl}$  aq. will precipitate the  $\text{Al}$ , probably as a mixture of hydroxide and phosphate; and the yellow colour of the filtrate from this precipitate will indicate the presence of  $\text{Cr}$ . This may be confirmed by acidifying and adding  $\text{H}_2\text{SO}_4$  aq. to reduce the chromate to green chromium salt. Traces of  $\text{Cr}$  and  $\text{Al}$  may be detected by this means in presence of large quantities of  $\text{PO}_4$  and  $\text{Fe}$ ; and the damage to the Pt. foil is so small that the same piece may be used many times without perceptible injury.

For the investigation of the behaviour of *cupric phosphate* with various reagents, the substance was reprecipitated as a sky-blue powder by adding  $\text{Na}_2\text{HPO}_4$  aq. to  $\text{CuCl}_2$  aq. According to Steinschneider (Journ. Chem. Soc. 60, 1423), the precipitate thus obtained may vary in composition under different circumstances, but is likely to consist of a double salt of  $\text{Cu}_2(\text{PO}_4)_2$  and  $\text{NaCl}$ . We found the precipitate to be soluble in  $\text{CuCl}_2$  aq. and also in  $\text{CuSO}_4$  aq. to a perceptible extent. This was proved by adding a litre  $\text{Na}_2\text{HPO}_4$  aq. to excess of  $\text{CuCl}_2$  aq., and also of  $\text{CuSO}_4$  aq., filtering and testing the filtrate for  $\text{PO}_4$ ; and also by adding only a drop or two of  $\text{Na}_2\text{HPO}_4$  aq. to  $\text{CuSO}_4$  aq., and shaking when the precipitate first formed was redissolved.

Cupric phosphate is said to be decomposed by hot water under pressure (Watt's Diet. 1894, Art. Phosphates). In order to investigate this property, the precipitate, obtained as above, was filtered through calico and stirred with boiling water repeatedly in a large beaker. The precipitate was allowed to settle after each treatment, and the supernatant liquid syphoned off and tested for  $\text{Cl}$  and  $\text{PO}_4$ , the process being repeated eight times.

The following observations on the relative quantities of  $\text{Cl}$  and  $\text{PO}_4$  present in the wash water after each treatment, show that the cupric phosphate precipitate was hydrolysed by hot water under ordinary atmospheric pressure:—

1st treatment with hot water ..	$\text{Cl}$ more than $\text{PO}_4$ .
2nd " " " "	"
3rd " " " "	.. $\text{Cl}$ getting less, $\text{PO}_4$ increasing.
4th " " " "	.. $\text{Cl}$ nearly absent, $\text{PO}_4$ still present in quantity.
5th " " " "	.. Trace of $\text{Cl}$ , $\text{PO}_4$ present in large amount.
6th " " " "	.. Trace of $\text{Cl}$ , $\text{PO}_4$ about the same.
7th " " " "	.. Faint trace of $\text{Cl}$ , $\text{PO}_4$ about the same.
8th " " " "	.. Free from $\text{Cl}$ , $\text{PO}_4$ still present in large amount.

During the process of washing the precipitate altered greatly in appearance. It became much denser, settled quickly, and gradually changed in colour from sky blue to light grass-green. On boiling the precipitate, left after the above washings, with water, much  $\text{PO}_4$  was dissolved therefrom.

Steinschneider (*ibid*) states that on washing normal cupric phosphate with water, a basic phosphate of the composition  $4\text{CuO} \cdot \text{P}_2\text{O}_5 \cdot 11\text{H}_2\text{O}$  is obtained.

In order to try and obtain this compound, we boiled the precipitate with water for about 9 hours under an inverted condenser, the wash water being changed three times during this period. After this treatment further washing did not remove any  $\text{PO}_4$  or other soluble matter, and the precipitate had therefore arrived at a state of constant composition.

It was dried at  $100^\circ \text{C}$ , and then 1 gram. was taken for analysis and was further dried at  $100^\circ \text{C}$ , until the weight was constant. The resulting powder—0.9952 gram. yielded 0.6620 gram. of  $\text{CuO}$  by hydrolysis with  $\text{KHO}$  aq. (see below) = 66.52 per cent.  $\text{CuO}$ ; and the filtrate, acidified with  $\text{HCl}$  aq. and treated with  $\text{NH}_4\text{HO}$  aq. and magnesia mixture, gave 0.4630 gram.  $\text{Mg}_2\text{P}_2\text{O}_7$  = 29.67 per cent.  $\text{P}_2\text{O}_5$ .

These results would indicate the presence of—

$$100 = (66.52 + 29.67) = 96.19 \text{ per cent. } \text{H}_2\text{O}.$$

The percentage of combined water was estimated directly by the loss of weight which the powder, dried at  $100^\circ \text{C}$ , suffered on further heating.

0.4980 gram. lost 0.0020 gram. after being heated for two hours at  $130^\circ \text{C}$ , 0.0010 gram. after an hour at  $170^\circ \text{C}$ ; and a further loss of 0.0150 gram. took place during ignition at a dull red heat over the luminous Argand flame. After this the weight remained constant.

The percentage of combined water thus estimated = 3.62. The actual percentage composition of the precipitate found and that corresponding to the formula  $4\text{CuO} \cdot \text{P}_2\text{O}_5 \cdot 11\text{H}_2\text{O}$ , are as follows:—

	Found.	Theory.
$\text{CuO}$ .....	66.52	66.46
$\text{P}_2\text{O}_5$ .....	29.67	29.77
$\text{H}_2\text{O}$ .....	3.62	3.77
	99.81	100.00

These results, therefore, support the statement of Steinschneider as to the composition of the precipitate after washing and drying at  $100^\circ \text{C}$ , till constant.

The tenacity with which the single molecule of water remains in combination with the basic phosphate is remarkable, since a dull red heat is necessary for its complete elimination. The ignited precipitate, consisting of—

was of an olive-green colour.

**Action of  $\text{KHO}$  aq. on Precipitated Cupric Phosphate.**—In the cold,  $\text{KHO}$  aq. did not appear to produce any change; but on boiling, the precipitate became dark coloured and seemed to consist of  $\text{CuO}$  only.

The action of  $\text{KHO}$  aq. was investigated quantitatively. 1 gram. of  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  was dissolved in hot water,  $\text{Na}_2\text{HPO}_4$  aq. added in excess, and the precipitate filtered off. This precipitate was transferred to a porcelain dish, excess of  $\text{KHO}$  aq. added, and the mixture boiled for some time. The dark-coloured precipitate was filtered off, washed free from alkali, dried, ignited, and weighed.

Weight of precipitate obtained..... 0.3179 gram.

Theoretical weight of  $\text{CuO}$  obtainable from

1 gram.  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ ..... 0.3189 "

Therefore cupric phosphate is completely hydrolysed by  $\text{KHO}$  aq.

**Properties of Bismuth Phosphate,  $\text{BiPO}_4$ .**—Bismuth carbonate was added in excess to  $\text{HCl}$  aq., so that the solution contained no free acid. The solution was filtered,  $\text{CO}_2$  boiled off from the filtrate, and  $\text{Na}_2\text{HPO}_4$  aq. added in excess.

**Solubility of  $\text{BiPO}_4$  in  $\text{BiCl}_3$  aq.**— $\text{BiCl}_3$  aq., prepared as above by filtration from excess of carbonate, possessed an acid reaction.  $\text{Na}_2\text{HPO}_4$  aq., added drop by drop, produced a precipitate which dissolved in the excess of  $\text{BiCl}_3$  aq. Also precipitated  $\text{BiPO}_4$  was added to excess of  $\text{BiCl}_3$  aq., and the solution filtered. The filtrate contained  $\text{PO}_4$ , showing that  $\text{BiPO}_4$  is somewhat soluble in  $\text{BiCl}_3$  aq.

The precipitated  $\text{BiPO}_4$  was washed in a similar manner to the cupric phosphate precipitate, and the wash water tested.

1st treatment .....	$\text{Cl}$ and $\text{PO}_4$ about the same.
2nd " .....	$\text{Cl}$ and $\text{PO}_4$ both diminished.
3rd " .....	Traces only of $\text{Cl}$ and $\text{PO}_4$ .
4th " .....	Neither $\text{Cl}$ nor $\text{PO}_4$ present.

So that  $\text{BiPO}_4$  was not hydrolysed by hot water; and when boiled with water for some time, no  $\text{PO}_4$  was abstracted.

By boiling with  $\text{KHO}$  aq. and filtering, a fair amount of  $\text{PO}_4$  was obtained, showing hydrolysis to be considerable. A similar treatment with  $\text{NH}_4\text{HO}$  aq. extracted some  $\text{PO}_4$ , though the action was not so pronounced as in the case of  $\text{KHO}$  aq.

**Quantitative Investigation of the Action of  $\text{KHO}$  aq. on  $\text{BiPO}_4$ .**—A weighed quantity of pure  $\text{Bi}_2\text{O}_3$  was dissolved in the least possible quantity of  $\text{HCl}$  aq.; excess of  $\text{Na}_2\text{HPO}_4$  aq. was then added to the solution, and the precipitate filtered off and transferred to a large porcelain dish.  $\text{KHO}$  aq. was added, the liquid and precipitate boiled for some time, the latter allowed to settle, and the supernatant liquid carefully decanted through a filter. The residue in the dish was boiled with fresh  $\text{KHO}$  aq., the liquid again decanted, and the precipitate washed free from alkali by decantation and transferred to the filter. The residue was straw-coloured. It was dried on the filter and ignited in a porcelain crucible until the weight was constant. If  $\text{BiPO}_4$  is completely hydrolysed by  $\text{KHO}$  aq., then the precipitate obtained should weigh the same as the  $\text{Bi}_2\text{O}_3$  originally taken, since it has the same composition:—

Weight of $\text{Bi}_2\text{O}_3$ taken .....	0.8395 gram.
" precipitate obtained .....	0.8378 "

Therefore the hydrolysis of  $\text{BiPO}_4$  by  $\text{KHO}$  aq. is complete.

**Properties of Lead Phosphate,  $\text{Pb}_3(\text{PO}_4)_2$ .**—This substance was obtained as a heavy white precipitate by adding excess of  $\text{Na}_2\text{HPO}_4$  aq. to  $\text{Pb}(\text{NO}_3)_2$  aq.

To try if  $\text{Pb}_3(\text{PO}_4)_2$  is soluble in  $\text{Pb}(\text{NO}_3)_2$  aq., some of the well-washed precipitate was boiled with  $\text{Pb}(\text{NO}_3)_2$  aq. and filtered. The filtrate did not give any yellow precipitate or colour with ammonium molybdate solution, proving that  $\text{Pb}_3(\text{PO}_4)_2$  is insoluble in  $\text{Pb}(\text{NO}_3)_2$ .

The behaviour of  $\text{Pb}_3(\text{PO}_4)_2$  with hot water was examined as in other cases. The precipitate was washed four times by decantation, and then the wash water from the fifth washing was tested for nitrate and phosphate, neither of which was found. Another treatment yielded not a trace of either nitrate or phosphate. Hence  $\text{Pb}_3(\text{PO}_4)_2$  is not hydrolysed by hot water. The precipitate was also boiled with water for some time, and the filtrate yielded only a slight yellow coloration with the molybdate solution. So that  $\text{Pb}_3(\text{PO}_4)_2$  is scarcely attacked by continued boiling with water.

**Action of  $\text{NH}_4\text{HO}$  aq.**—Some lead phosphate was digested with dilute ammonia in the cold. The filtrate showed small quantities of  $\text{PO}_4$  and of  $\text{Pb}$ . Since  $\text{Pb}(\text{OH})_2$  is soluble in  $\text{NH}_4\text{HO}$  aq., the presence of lead was to be expected. On boiling with  $\text{NH}_4\text{HO}$  aq. for some time, large quantities of  $\text{Pb}$  and of  $\text{PO}_4$  were found in the filtrate.

**Action of  $\text{KHO}$  aq.**—Only a slight action took place in the cold, but on boiling with aqueous potash the precipitate was entirely dissolved. As in the case of  $\text{AlPO}_4$ , no hydrolysis could be demonstrated, and we cannot say whether  $\text{Pb}_3(\text{PO}_4)_2$  dissolves in  $\text{KHO}$  aq. as such, or whether it suffers hydrolysis previous to solution.

## DISCUSSION.

The CHAIRMAN said it would be obvious to everyone present that the observations made by Mr. Caven were of special interest to analytical investigators. They had a paper to follow, which was an extremely important one to the borough of Derby, on the purification of sewage, and he thought it would be best to have the paper just read in print before they began to discuss it. In that way they possibly would also gain a little by others, who were not then present, joining in the discussion.

SESSION 1896-97.

Meeting held in Edinburgh on Tuesday, Dec. 22nd, 1896.

MR. JOHN TAIN, F.R.C.S., IN THE CHAIR.

## THE REMOVAL OF ORGANIC MATTER FROM PEATY WATER.

BY J. B. READMAN, D.S.C., F.R.S.E.

THE treatment of water by the method about to be described is not new. What may probably be novel in it was the attempt to purify water, highly coloured by peat, in a large service reservoir, from which, while the treatment was going on, a considerable area was being served with water.

In May 1895, a large reservoir of about 113 acres in extent, constructed by direction of the County Council of Linlithgow, was opened at Forrestfield, near Bathgate. Its greatest depth is about 24 ft., and its holding capacity is about 200 million gallons. Nearly one million gallons are drawn off every day.

It was found before completion that the capacity of the lake was not sufficiently large, and a considerable quantity of peat, which forms part of the bottom, had to be excavated. The result of this was to expose the freshly-cut and puddled-up surface to the solvent action of the water when the lake was filled with water. Owing to the urgent necessity for assessment purposes of having the reservoir filled and the water turned on by a certain date, little or no time could be spared to cover up or otherwise deal with this peaty bed, and the consequence was the lake was filled soon after it was deepened.

It was not long before the people in the distributing area discovered that the new supply was highly discoloured and strongly impregnated with a peaty flavour and odour, and, besides, was most unpalatable, and a general complaint arose that the water was unfit to use for potable purposes.

As Public Analyst for Linlithgowshire, where the reservoir is situated, samples of water both from the feeder and from the lake were, for the first time, sent to me for examination. Previous to this, and as far as I am aware, no chemical examination, either of the stream or of the springs had been supplied to, or demanded by, the Local Authority. I found that the Forrest Burn water was of fairly good quality and practically free from peat, at that time, i.e., in the spring of the year, but that the water of the reservoir was highly coloured and practically uniformly so in this respect all over its area.

On the 4th of June of last year (1895), just about one month after the water was formally turned on, I reported on the water as follows:—

June 1895.

Total solids.....	7.63 grains per gallon.
Volatile residue.....	2.10
Saline .....	5.53
Free ammonia.....	0.0042 " "
Albumenoid ammonia .....	0.0210 " "
Nitrates and nitrites .....	None.

Combined chlorine .....	1.86 grains per gallon.
Total hardness .....	2.10
Temporary .....	2.10
Permanent .....	None.

Iron.....	0.0098 " "
Phosphates.....	Very faint traces."

The water had a faint alkaline reaction, was of a brown peaty colour, and contained a small quantity of suspended matter. The water was soft, and free from animal organic pollution, but it contained a large quantity of dissolved vegetable matter (peat), which rendered it dark brown in colour and gave the water, when heated, the odour of decayed leaves. In our opinion, the presence of so much peaty matter made the water in its then condition unfit as a supply for general domestic purposes and specially so for potable purposes.

The excessive amount of peat is indicated, not only by the colour of the water, but also by the high figure for albumenoid ammonia. Waters of this class (containing even less dissolved vegetable matter than this one under examination) have been known to give rise to outbreaks of diarrhoea.

We had made experiments in the laboratory from time to time on the water, and ascertained that the addition of about 3½ grains per gallon, or 1 lb. of alum for every 2,000 gallons of water, threw out practically all the colouring matter from the water, and that this result was accomplished during the course of one night or, say, after about 12 hours' standing.

As economy had to be considered, my first endeavour was to get a cheap source of alumina, and this was readily obtained from alum cake, which was guaranteed to contain 11 per cent. of soluble alumina and not over ½ per cent. of uncombined sulphuric acid. As the behaviour of the precipitate when present in quantity was uncertain, I thought it prudent to apply the alum in the initial stage as far from the outflow as possible, i.e., at the extreme west end of the lake, where the Forrest Burn enters. It was thus added nearly one mile away from the pipes which supply the district from the reservoir.

To carry this out a kind of rack made of spars of wood was constructed across the Forrest Burn. In reviewing this procedure one must keep in mind that the water was uniformly coloured all over the lake, but it was certainly very much less coloured than when I first reported on it. The treatment was begun on 30th March last by adding to the rack 30 cakes per day, i.e., about 20 cwt. The effect was most rapid: the hydrated alumina precipitate, as expected, formed a lake with the colouring matter, and within a few yards of the spot the precipitate had subsided and the water above and around was clear, sparkling, and colourless. The addition of alum at this place was continued for a week, and then we divided off the lake into five divisions by placing posts on opposite banks about equal distances apart. Thus Nos. I. were driven into the ground about 300 yards from the rack, Nos. II. were placed about 200 yards from Nos. I., Nos. III. about 200 yards from Nos. II., and so forth.

Success, so far, having emboldened us, we made, on the 7th April, an alteration of the place where the cake was added. In place of putting it all in the rack 18 cakes only were placed there, and the remainder placed just below the water on the bank at No. I. post. The practice was likewise started of drawing five samples from the reservoir every day, midway between each set of posts.

Up to now the alum was added entirely by the rack or by placing the cakes on the shore. Now a raft was constructed, in the form of a square, with a spar bottom, always under water, upon which the cakes were placed. This raft was anchored between posts Nos. II., and was, after an interval, moved eastwards, and finally came to rest between posts Nos. IV.

A month after the first addition of alum at the rack the water had immensely improved in colour and odour, and when the experiments were stopped two months from the commencement, the water was in every respect equal to that supplied to this city. The experiments consumed about 60 tons of alum cake, but it must be remembered

that much of this was expended on the over-cautious addition at the west end of the lake.

*Analysis of the Treated Water, June 1896.*

Total solids.....	6.79 grains per gallon.
Volatile residue.....	1.61
Saline.....	5.18
Free ammonia.....	0.0063 " "
Albumenoid ammonia.....	0.0077 " "
Nitrites.....	None.
Nitrates.....	Faint trace.
Combined chlorine.....	0.74 grains per gallon.
Total hardness.....	3.6
Temporary.....	0.5
Permanent.....	3.1
Iron.....	None.
Phosphates.....	None.

The water had a neutral reaction, but when boiled was faintly alkaline. It was free from odour when heated to 100° F. Viewed through a 2-ft. tube, it showed but a trace of yellow colour, and had a bright, clear, and colourless appearance when seen in bulk.

Now, it may be asked: Has the water gone back in colour? or is it still as colourless as when the experiments were considered at an end, about the end of May last? In reply, I must say that the water has not maintained its colour in the reservoir. It will be remembered that the spring of this year was a remarkably dry one, it was then the treatment began, and during its continuance scarcely any rain fell; the consequence was the Forrest Burn flowed into the lake nearly colourless, and there was no washing of the peaty banks of the gathering ground by heavy downpours.

I was not then aware that the Forrest Burn passed through a district accessible to drainage from peat. When the rain set in the burn came down highly charged with peat, and naturally had a serious effect on the colour of the whole reservoir.

The remedy, however, lies with the local authorities. If they are content with the water as it now is, which is undoubtedly much improved in colour, it is needless to go to any further expense; if, however, they want a clear and colourless supply, it is only necessary to resume and continue the alum treatment by the raft system.

As to the cost of the purification process, it was ascertained by experiment that 3½ grains per 1,000 galls. threw all the peaty matter out of solution—this is equivalent to 1 lb. for every 2,000 galls. treated,—and as one million galls. are daily drawn off, the quantity of alum cake required would be 500 lb. or, say, 5 cwt. per day. This quantity would cost about 7s. 6d., or, with occasional attendance, say, 10s. a day. In summer weather, or rather at periods when there is a low rainfall, the treatment could be suspended altogether.

I estimate that a cost of about 150l. a year would suffice to effect this result.

In regard to the action of the water on lead, no experiments were made at the time: this was because of the fact of water being almost entirely supplied to the villages by means of stand-wells in the streets. Very few houses had the water introduced; hence no lead pipes. Since then, however, we have made a number of experiments on the point, and have found that the reservoir water has certainly more action on lead than Edinburgh water; but what is satisfactory is that the treated water has only about half the solvent power of the untreated water.

#### DISCUSSION.

Mr. LAINO remarked that the simplicity and the economy of the process which Dr. Readman had applied in his experiments should lead to its general adoption, as a glance at the specimens of the water and the results of analysis, before and after treatment, showed that the author had successfully solved the problem on a large scale. He expressed his regret at hearing that the water had not remained colourless, due to the influx of peaty water; and he suggested that the water might be subjected to a purifying process before reaching the reservoir. A spent shale bed would form a capital filter, and would supply

the alum perhaps, but he feared the water would dissolve out other salts, such as iron, &c., which it would not be advisable to have present.

Mr. GRAY asked the author whether the purified water contained alum, and if not, how this was avoided. He further asked if Dr. Readman was of the opinion that the water would have remained clear in the absence of any influx of peaty matter, and whether the object he had in view in carrying out the process was not only to purify the water in the reservoir, but also to protect the underlying peat, by means of the alumina-lake deposited in it, from the solvent action of the water. He also asked if the colour of the water after treatment had developed slowly, or if there had been any sudden accession of colour after heavy rainfalls, as an answer to these questions might give some information as to the efficiency of the alumina-lake in retarding or preventing further contamination.

Dr. READMAN stated that the water was free from alum, and that the treatment was stopped as soon as the organic matter was carried down; excess of alum was thus avoided. His object in applying the process was not only to purify the water in the reservoir, but also, by the aid of subsequent treatment, to provide a protecting layer to prevent solution of colouring matter from the peat. He was misled at the time of the experiments by his understanding that the Forrest Burn was not accessible to peaty drainage; this view was apparently confirmed by the appearance of the water, which was then clear and colourless. He was not able to say whether the colour of the present water had developed slowly or quickly, as he had not visited the reservoir since the treatment was stopped.

## Obituary.

### JOSEPH D. WEEKS.

MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY.  
OF THE UNITED STATES GEOLOGICAL SURVEY.  
FORMERLY PRESIDENT OF THE AMERICAN INSTITUTE OF MINING ENGINEERS AND METALLURGISTS.  
EDITOR OF THE *American Manufacturer*, &c.

THOSE members of the Society of Chemical Industry who attended the Annual General Meeting of 1895, held in Leeds, and were present at the annual dinner of the Society, will doubtless still retain in memory a more or less vivid impression of the eloquent words of him, now the subject of this brief notice, though then the welcomed guest of the Society. It seems truly but a brief space which intervenes between that welcome and this adieu. Mr. Joseph D. Weeks was stricken with apoplexy on December 26th, 1896, and died within a few hours after the seizure at Pittsburg, Pennsylvania. He was born in Lowell, Mass., in 1840, and, after completing a scientific course of study at Wesleyan University, Middletown, Conn., he entered the ministry. After the war he proceeded to Cincinnati, and subsequently became a newspaper writer. In 1872 he went to Pittsburg, and was connected with the *American Manufacturer*, with which the *Iron World* was soon afterwards united. In 1875, becoming associate editor of the *Iron Age*, during the 10 succeeding years he had charge of the Western department of that journal. In 1883 he became secretary of the Western Pig Iron Association, which office he continued to hold up to the time of his decease. In 1886 he assumed the control of the *American Manufacturer*. For the United States Census of 1880, Mr. Weeks prepared the details and figures entitled "The Manufacture of Coke" and "The Manufacture of Glass." In addition to this he prepared the entire Volume XX. of the United States Census of 1880, entitled "Statistics of Wages in Manufacturing Industries, with Supplemental Report on Strikes, Lock-outs, and Trade Societies."

In 1885 he began his work for the United States Geological Survey, making reports yearly on the manufacture of coke, petroleum, natural gas, and the production of manganese. For the Census of 1890 he prepared three reports—Crude Petroleum, Natural Gas, and

Manganese; and in the Department of Manufactures three reports—Coke, Glass, and a work on Petroleum Refining, the latter being the first of its kind ever published by the Government. For many years Mr. Weeks was a member of the American Institute of Mining Engineers, and was President of that body during 1895.

It is with much regret we have within two months to bid adieu to two distinguished members of our Society in the United States, Mr. Alfred H. Mason and Mr. Joseph D. Weeks: and in stretching out the hand of fraternal sympathy to our American Section and fellow-members, probably no more fitting words can be found with which to close this notice, than those with which Mr. Weeks opened his speech at Leeds on the occasion already referred to:—

"We speak the same language, we have the same thoughts, we have in many respects the same history, we have the same hopes, we have the same aspirations, and I think that in the future, as humanity marches onward and seeks higher aims and cherishes loftier aspirations, the Americans and the English will be found side by side through all the centuries."—W. S.

## I.—PLANT, APPARATUS, AND MACHINERY.

*Valve for Cylinders containing Compressed or Liquefied Gases.* E. Ducretet and L. Lejeune. *Comptes rend.* 1896, 123, 810—811.

The valve recommended by the authors is shown in the accompanying figure. The function of the new valve is to prevent the rapid and explosive exit of the compressed gas when the plunger V is suddenly unscrewed. This is accomplished by the introduction of a valve S, which has an adjustable permanent opening, thus preventing the violent escape of gas, whilst it does not interfere with the rapid charging of the cylinder.

\* Any of these specifications may be obtained by post by remitting 8d.—the price now fixed for all specifications, postage included—to Sir Henry Reader Laek, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

### PATENTS.

*Centrifugal Machines, Impts. in, for Drying Sugar and other Granular Substances.* W. P. Abell, Essequibo. Eng. Pat. 22,900, Nov. 29, 1895.

See under XVI., page 56.

*Meters [Distillery] for Measuring Spirits and Distillates, Impts. in.* C. F. Chapp, Basse Terre, Guadeloupe. Eng. Pat. 23,849, Dec. 13, 1895.

An apparatus for recording the total weight and average alcoholic strength of the produce from a still. It comprises a scoop-shaped scale-pan, overhanging and forming part of which is a trough-shaped chute, into which the spirit from the still is discharged by a pipe ending in a T head, thence overflowing into the scale-pan. The latter, being suitably counterpoised, oversets when loaded to a predetermined degree (with 1—10 litres) and discharges its contents: and in order that at this stage the overflow from the chute may cease, the trough is made shallow at the discharge end, but deep elsewhere, and is thus able to hold and retain the liquid coming from the still-pipe until the pan has resumed its normal position. The liquid discharged from the pan flows into and completely fills a small tank fitted with two siphons—a large one, which transfers the bulk of the spirit to the storage vessel, and a smaller one, which serves to take a "sample" of the liquid. The consecutive samples are, of course, collected in a separate vessel, and, united, form the average sample. The number of fillings of the scale-pan is recorded by a counting machine actuated by a float situated in the above-mentioned tank. Two testing chambers are provided at the inlet and outlet ends, respectively, of the meter, fitted with draw-off cocks, thermometers, alcoholometers, &c.—H. T. P.

*Filtering Liquids and Impregnating the same with Gases, Impts. in Apparatus for.* [Impregnating Filter.] W. Raydt, Stuttgart, Germany. Eng. Pat. 24,835, Dec. 27, 1895.

"An impregnating filter, such, that during the forcing through of the liquid, a continuous admission of the gas under pressure takes place into an ante-chamber. This is in direct communication with the filter chamber, and is traversed by the liquid in a finely divided state, on its way to the filtering receptacle. The purpose of this is to effect both the highest possible degree of impregnation as well as a rapid and thorough filtration."

*Apparatus for bringing to a desired Temperature Articles of all kinds, more particularly Wines: An Improved.* C. Fischer, Hamburg. Eng. Pat. 20,869, Sept. 21, 1896.

A DOUBLE-WALLED, bucket-shaped vessel fitted with a lid (also jacketed) and provided with a false bottom carrying a central tube of perforated metal. The bottles of wine, &c. are placed in the annular space round the central tube, and the latter is charged with ice, or a flame is maintained in it, according to requirements.—H. T. P.

*Filters for Wines, Spirits, and other Liquids: Impts. in.* W. Elze, Kostritz Thüringen, Germany. Eng. Pat. 21,010, Sept. 22, 1896.

The filter consists of a cylinder mounted on trunnions, and the filtering material, which consists of cellulose pulp, is placed between two perforated plates fixed at one end of the cylinder.—A. L. S.

*Apparatus for Heating [Sterilising] and Cooling Liquids, Impts. in.* W. F. E. Casse, Copenhagen. Eng. Pat. 22,060, Oct. 5, 1896.

The sterilising apparatus is intended for continuous work, and consists of a system of parallel jacketed tubes, connected in series. The outer jackets are divided into two sets, traversed by hot and cold water respectively, whilst the liquid to be sterilised flows continuously through the inner tubes, but in an opposite direction. The inner tubes are so connected as to be readily accessible for cleaning purposes.—H. T. P.

*Distilling Apparatus, An Improved.* S. S. Bromhead, London. From C. Dicker, Brussels. Eng. Pat. 20,292, Oct. 28, 1895.

The distilling apparatus consists of two cylindrical casings fitting one above the other, the lower of which, A, contains the liquid to be distilled, and is heated by a fire, while the upper, K, acts as a cooler. The latter is provided with a conical bottom, B, and the condensed water flowing down on the inner side of this is caught in an annular hollow dripping channel, R, and is led away through a tube, C.

The water for use in the cooler is led by a pipe, D, to the interior of the dripping channel, and thence passes upwards through an opening (not shown) to the mass of water above the conical bottom, finally overflowing through the vertical outlet channel, S, to the cock E. This water may be caught in a funnel, E', and be led to the lower vessel, thus acting as an automatic feed thereto. For obtaining alcohol, ether, essences, extracts, and the like, the upper and lower vessels

are screwed together, and the lower vessel has suspended therein a water-bath, G, containing the alcohol or ether, upon which may be placed a sieve, H. By the use of this arrangement, "any desired extracts and essences can be prepared by means of alcohol, ether, &c." In a modification, the upper cooling vessel may be formed as a double cone, and the cooling liquid therefrom removed by means of a pipe from the apex, and led to a special device for regulating the level of the liquid in the lower or distilling vessel.—R. S.

*Solid and Pasty Substances, Apparatus for Treating with Gases at Elevated Temperatures.* L. Mond, Regent's Park, London. Eng. Pat. 23,665A, Dec. 10, 1895.

The apparatus consists of an upright chamber, A, divided by trays or partitions, B B', into a number of sets of superposed compartments, A', each set consisting of a heating compartment, E, and two reacting compartments. Each heating compartment is connected by a fine, F', having a valve, f, to a combustion chamber, G, for gaseous fuel, and is provided with a vertical partition, so that the said gases must pass completely around the compartment before passing away through a second fine, similar to and placed behind F', to the chimney shaft. By means of the valves f each compartment may be independently heated. The

reacting compartments are chambers down which the solid material is caused to pass by rotary stirrers or scrapers, J J', of which the stirrers J, acting on the trays B, tend to move the material from the centre to the periphery, where it falls through the openings C to the tray B' below. The stirrers J' on this tray move the material from the periphery towards the centre, so that it falls through the opening I on to the next tray below. The gases enter at P' and pass

upwards through all the reacting compartments, finally escaping through the outlet P. The treated product is discharged through a pipe, N, into a conveying worm, O, or directly into receptacles. The lower reacting compartments may be cooled instead of heated, by passing cold air or water through the branch pipes and valves M into the compartments E.—R. S.

*Wet Steam, Method of High Superheating.* [Drying and Superheating.] W. Schmidt, Ballenstedt-on-Harz, German Empire. Eng. Pat. 1520, Jan. 22, 1896.

The method consists in first letting the wet steam pass through a coil, wherein it is dried, or dried and slightly superheated, by the coolest portion of the waste gases of a furnace, whilst flowing in a direction opposite to that of the said gases, and then conducting the dried steam into a second coil, wherein it is properly superheated by the hottest portion of the waste gases whilst flowing in the same direction. In the apparatus described, the two coils encircle a flue through which the waste gases pass, the first coil being arranged above the second, and connected at its lower end to the lower end of the latter, so that steam passed downward through the first coil will pass upward through the second.—R. A.

## II.—FUEL, GAS, AND LIGHT.

*Coal, The Supposed Ontario.* A. McCharles. Eng. and Mining J. 1896. 62, [22], 512.

It was at first supposed that a discovery of coal had been made in Ontario. The mineral now proves to be merely "anthraxolite," which is of little economic value, except for use on the spot as fuel. An analysis of the mineral given in the Government Report by Prof. Coleman shows the following results:—Hygroscopic moisture, 2.67 per cent.; volatile organic matter, 4.78 per cent.; fixed carbon, 55.85 per cent.; sulphur 1.06 per cent.; ash, 36.5 per cent.; total, 100.86 per cent. Other assays show varying amounts of ash, but none less than 20 per cent. The substance in its unexposed state is very black and lustrous, and readily breaks up by hand into thin layers and small cubes. It burns well with a short reddish flame when started with wood, and gives a good heat, leaving an ash resembling reddish sand. If the draught is not very strong, the lumps burn only on the outside. It is stated to have been successfully used in forging iron. The above report refers to the deposit 17 miles west of Sudbury, and there is now stated to be another large deposit of the same material 30 miles east of that town.

—A. W.

*Thiocyanides from Spent Gas-purifying Materials.* V. Hölbling. Mitt. tech. Gewerbe-Museums in Wien, 1896, 245–253.

MARASSE proposed (Ger. Pat. 28,137, 1882) to obtain calcium thiocyanide by heating the residue, after extraction of the spent material with water to remove the soluble ammonium salts,—with lime and water in closed vessels at 100° C. Marasse believed that calcium ferro-cyanide and calcium sulphide were first formed, and that these then reacted on one another, forming calcium thiocyanide and iron sulphide.

The author finds that higher temperatures are necessary for the formation of calcium thiocyanide, and that the reaction is not so simple as Marasse believed. The reaction is probably most nearly expressed by the following equations, the formula  $\text{Fe}(\text{CN})_2$  usually assumed for the cyanide present in the residues in question being adopted:—

According to these equations, the proportions of the Prussian blue and sulphur entering into reaction are  $3\text{Fe}(\text{CN})_2:10\text{S}$ , or, practically, equal weights. But in the spent material the blue is only about 5 per cent. or less, whilst the sulphur is about 25 per cent.; and the excess of sulphur is lost as iron sulphide. Some, at least, of this loss

can be obviated by adding to the spent material the waste blue ("Hell-blau," or mixture of Prussian blue and gypsum), generally thrown away as a waste product in the preparation of Prussian blue and yellow prussiate from spent gas-purifying materials.

Attempts to obtain the cyanide in the more commercially useful form of alkaline thiocyanide by replacing the lime by caustic alkali (as suggested by Marasse), or by alkaline carbonates, were not successful enough to be commercially valuable. With the caustic alkalis the cost would be prohibitive, and it was also found very difficult to filter off the solution containing potassium sulphides from the residual iron sulphide. With alkaline carbonates (potash was used) heating for 12 hours under 3 atmospheres pressure was necessary, and even then about 30 per cent. of the blue remained unacted on. Complete decomposition of the blue could not be effected. It is just possible that this carbonate process might be used in works where yellow prussiate is made, the undecomposed blue being worked up for the prussiate.

Attempts to employ ammonia led to no results likely to prove commercially applicable.—L. T. T.

## PATENTS.

[Illuminating Gas.] *Production of Gases from Hydrocarbon Oils, Impts. in the.* R. E. Middleton, London. Eng. Pat. 15,254, Aug. 14, 1895.

THE oils are placed in a closed vessel, which contains carbons suitable for producing one or more electric arcs on sending a current through. The oils are thereby vaporised; they are then washed, and led to a gas-holder. The gases may be mixed with ordinary coal-gas or other gases. The residuum of the oils may be used as fuel.—R. S.

*Products of Combustion, A New or Improved Apparatus [Combination with Two Gas-meters] for Estimating the Carbonic Acid or other Constituents in Gases or.* G. Craig, Cumnock, Ayrshire, N.B. Eng. Pat. 22,363, Nov. 22, 1895.

See under XXIII., page 65.

*Earth Metals, Impts. in the Manufacture or Production Electrolytically of Coatings composed of Oxides of the.* [Mantles.] R. Langhans, Berlin, Germany. Eng. Pat. 23,137, Dec. 3, 1895.

In this process an electrolytic coating of a hydroxide of the earth metals is formed on a conducting foundation, and is subsequently converted into the oxide by calcination. The deposition is preferably effected in a cylindrical vessel containing a diaphragm forming or being lined with an insoluble electrode, within which is a saturated solution formed by dissolving in a concentrated solution of a neutral earth salt, such as the sulphate or nitrate, earthy hydrates precipitated in the cold, and well washed, while between the diaphragm and the outer vessel is a solution of the hydrated oxide or carbonate of the same earth metal. A thin platinum cylinder forms the anode, and the cathode is the body to be coated—say, an incandescent mantle formed of a gauze cone of platinum, gold, carbon, or other suitable conductor. When sufficiently coated, the mantle is removed from the bath, washed, dried in air free from carbonic acid, and calcined by gradually raising the temperature. The minimum current density per square centimetre for 20 per cent. solutions of the salts of zirconium and thorium is 1.66 ampères, of yttrium 1.25 ampères, and of aluminium 0.75 ampère, but double this current density is preferably employed. To render the deposit less dense, the solution of the basic salt may be prepared by adding ammonia to the aqueous solution of the neutral salt until

the hydroxide which separates out is redissolved; and this is continued as long as re-solution occurs. Instead of ammonia, basic derivatives, such as amines and the like, as a sodium and potassium hydroxides, may be used. Where a thick coating is required, an alcoholic solution of the basic earth salt—say, nitrate of thorium—is preferably employed, in conjunction with an alcoholic solution of ammonia. To prevent cracking, the foundation may be covered with a netting or winding of combustible fibres, such as cotton, silk, or the like, which will be destroyed during calcination, leaving the oxide coating porous; or the hydroxide deposit may be converted, previous to calcining, into organic or inorganic salts, preferably the latter, which will yield oxides on heating.—G. H. R.

*Earthy Oxides, Impts. in the Manufacture or Production Electrolytically of Coatings composed of.* [*Incandescent Mantles.*] R. Langhans, Berlin, Germany. Eng. Pat. 24,546, Dec. 21, 1895.

1. A mantle constructed of an electro-conductive material, such as platinum, gold, or carbon, forms the cathode in a bath composed of a dilute solution of, say, 3 per cent. of an earthy hydroxide, soluble in water, such as thorium. An insoluble anode is employed, and the current density is about 3 amperes per 100 sq. cm. Directions are given for the preparation of the hydroxides of thorium, and in the term earthy hydroxide are included the hydroxides and the oxides of both the earth metals proper and the earth alkali metals. When the mantle is sufficiently impregnated, it is removed from the bath and calcined, and in order to prevent the coating cracking during calcination, and to render it porous, there is dissolved in the bath an organic base or alkaloid, which will be deposited jointly with the hydroxides of the earth metal on the negative electrode, and be subsequently destroyed on the mantle being calcined. Instead of dissolving opium, morphine, bases of the veratrine class, &c., in the bath, the mantle may be covered with combustible fibres previous to electrolysis, as in Eng. Pat. 23,137, 1895 (see previous abstract); or the hydroxide deposited may be transformed before drying and calcining into a salt capable of parting with its acid under the action of heat.—G. H. R.

*Gas, Combustible; Impts. in the Manufacture of.* [*Use of Refuse.*] L. Denayrouze, Neuilly (Seine), France. Eng. Pat. 23,856, Dec. 12, 1895.

A CYLINDRICAL vessel or retort is used for making combustible gas by the distillation of waste material, such as waste fatty matters, residues from petroleum distillation, tar, sewage matters, feces, &c.—L. T. T.

*Incandescent Lamp for the Combustion of Paraffin Oil and other Liquids.* A. M. Clark, London. From A. Meyenherg, M. Wendorf, and S. Henlein, Frankfurt-on-the-Maine. Eng. Pat. 23,873, Dec. 12, 1895.

THE reservoir of the lamp consists of two chambers, the inner one containing benzoline, and the outer one, which completely surrounds the inner chamber, containing paraffin oil. Air under pressure can be supplied to both chambers from an india-rubber ball (situated in the hollow base of the lamp), which is inflated as often as required by means of a compressible india-rubber bulb situated on the outside of the lamp. The vaporising chamber to which the paraffin oil is raised from the reservoir by means of the compressed air is situated within the burner mouth-piece and the mantle support, and by leading the vapour produced down a small pipe which is bent upwards at its lower extremity, the upward rush of gas induces an indraught of air through holes provided round the surrounding banner-tube, in the usual way. The mixture of vapour and air then burns at the burner mouth-piece, which is provided with a conical cap of wire gauze as usual.

The benzoline is used merely to start the lamp. Air from the india-rubber ball is saturated with the benzoline, ascends by a small pipe to the burner mouth-piece, and is therefore allowed to burn long enough to so far heat the vaporising chamber that the paraffin oil can give a regular supply of gas.

By turning a two-way cock, the paraffin vapour reaches the burner just before the air saturated with benzoline, is turned off, so that the benzoline flame ignites the paraffin vapour, and, on the other hand, when extinguishing the lamp, the benzoline conduit remains open for a brief interval after the closing of the paraffin conduit, so that the paraffin vapour generated after the stoppage of the paraffin oil supply, may be consumed. To facilitate the use of the two-way cock, a pointer is fastened to its outer end at right angles to its length and moves over a graduated scale.—H. B.

*Incandescent Gas Lighting, Impts. in the Preparation and Production of Bodies ["Lucium"] for Use in what is known as.* P. Barrière, Paris. Eng. Pat. 24,003, Dec. 14, 1895.

THE patentee claims to have discovered in monazite sand a new body which he calls "Lucium," to be used in making mantles. The sand is fused with sodium carbonate to convert the metallic oxides into insoluble carbonates, lixiviated with water, the insoluble matter slowly calcined with sulphuric acid, the sulphates dissolved in cold water and precipitated by ammonia. The hydrates are dissolved in HCl, the solution neutralised, and precipitated with oxalic acid. The precipitated oxalates are treated with sulphuric acid, of which the excess is expelled, the sulphates are dissolved in cold water and again precipitated by ammonia. The gelatinous precipitate is filtered off, washed, and dissolved with sulphuric acid, the solution being allowed to stand from five to six hours, after addition of saturated sodium sulphate solution to precipitate Ce, La, and Di. After filtering, the solution is again precipitated by ammonia and the precipitate converted into sulphate, when the thorium is precipitated by potassium sulphate. The solution is filtered, and the "Lucium" precipitated by heating to boiling after adding concentrated sodium hyposulphite (thiosulphate) solution. The precipitate is washed, dissolved in hydrochloric acid, and the new body precipitated by means of ammonia, filtered off, and washed. It is then converted into nitrate and mixed with some nitrate of zinc solution. The patentee claims for use in incandescent gas lighting the new body, either alone or in combination with oxide of zinc or other body "capable of imparting power of radiation," and also claims the above-described process of purification of the body. (See Chem. News, 74, 212, 259, and 269.)—H. B.

*Charging Air with Combustible Matter [Carburetted Air] and applying it for Illuminating, Impts. in the Method of and Apparatus for.* L. Denayrouze, Neuilly, France. Eng. Pat. 24,381, Dec. 19, 1895.

AIR under a pressure represented by 30 to 40 ins. of water is sent through the mains and mixed, at the burner itself, with (a) a volatile liquid hydrocarbon, (b) a solid hydrocarbon, or (c) combustible dust.

(a.) The liquid is withdrawn by the outlet of the air passing over the outlet of a tube leading from the liquid receiver beneath the burner, and the spray and air are mixed by a fan before passing to the burner. (b.) The solid, such as naphthalene, is contained in a receptacle above the burner, and the air blown over its surface. The mixture passes to a chamber containing a rotating fan, where it is mixed with more air, and thence passes to the burner. (c.) The powder receptacle has a small feed roller at the bottom, which delivers a small regular quantity of powder, which is driven by the air jet to the mixing chamber and thence to the burner.—R. S.

*Mantles for Incandescent Gas Lighting, Impts. in.* A. and W. S. Taylor, Glasgow. Eng. Pat. 24,505, Dec. 21, 1895.

THE cotton mantle is washed in dilute solution of nitric acid or ammonium nitrate and then immersed in a "strong solution in water of oxide, nitrate, or sulphate of aluminium, ammonium bichromate, and zinc nitrate," in the proportion of about 70, 20, and 10 per cent. respectively. The aluminium salts may be replaced by beryllium salts, the bichromate by titanium salts, and the zinc nitrate by manganese nitrate. The mantle may then be dusted over with powdered sulphur or gunpowder and burned.—H. B.

*Glow Bodies for Incandescent Lamps* [*Rhodium Oxide*]. Composition to be used in the Manufacture of. G. Lowenberg, Berlin. Eng. Pat. 21,267, Sept. 25, 1896.

IN thoria-ceria mantles the introduction of a little "oxide of rhodium" permits a considerable reduction of the amount of ceria required. Thus a mantle containing thoria, 98·8 per cent.; ceria, 1 per cent.; and "oxide of rhodium," 0·2 per cent., emits as much light as one composed of thoria, 98 per cent., and ceria, 2 per cent. The claim is for a composition containing oxides of thorium and cerium and "one or more of the oxides of the gold group, as palladium, iridium, osmium, ruthenium, rhodium, and the like."

—H. B.

*Incandescent Gas or Oil Lighting* [*Incandescent Glass Chimneys*], Impts. in. N. T. M. Wilmore, Hampstead. From D. Little, Melbourne, Australia. Eng. Pat. 1524, Jan. 22, 1896.

ANY earths, minerals, &c., capable of incandescing under the action of heat are to be brought into minute subdivision and then incorporated with the substance of ordinary glass chimneys, so as to become incandescent when heated by an ordinary oil lamp or burner.—H. B.

*Lamps for Burning Hydrocarbon Oil or Spirit*, Impts. in or connected with. R. Kiesow, London. From A. Kiesow, Berlin. Eng. Pat. 1507, Jan. 21, 1896.

IN order to avert the danger of the accumulation in the lamp reservoir of an explosive vapour which might be ignited by the flame of the lamp, the patentee traps off the vapour by employing as a receptacle for the wick a descending tube, which at its upper end is hermetically fixed into the reservoir collar into which the burner is screwed. The tube passes downwards to within a short distance of the bottom of the reservoir, where it is spread out in the form of an inverted saucer, to meet the walls or bottom of the reservoir. The tubular wick chamber thus formed is provided at its lowest part with holes which allow the oil to flow into it from the reservoir; as these holes are always sealed by the oil in the lamp, no vapours from the outside reservoir can pass into the tube and so reach the burner. The supply of air to the reservoir, necessary to permit the proper flow of oil to the wick, enters through a hole in the filler-cap, and to prevent the outflow of the oil in the event of the lamp being upset, the cap is formed like a cylindrical box divided into two compartments communicating with each other, with the outside air, and with the reservoir by means of minute apertures.

—H. B.

*Obtaining Light* [*Liquid or Gaseous Hydrocarbon Lamps*], Impts. in Means for. F. Tatham, Lewisham Hill. Eng. Pat. 14,009, June 24, 1896.

Consists in supplying oxygen under pressure at the point where the hydrocarbon is to be ignited and burned. Three forms are shown: (a) where ordinary paraffin or like oil is used, (b) where a heavy liquid hydrocarbon is used, and (c) where a gas is employed. The flame in each case may impinge upon a pencil, pencils, or a plate of refractory incandescent material. In a the oil is drawn up by a wick, in b by the oxygen used with a sprayer nozzle. In the case of a, the wick tubes are cooled by water, and a water-circulating arrangement is shown and described.—R. S.

*Gas, Appliances for increasing the Illuminating Power of, under Combustion*. R. Lavender and W. Tice, both of London. Eng. Pat. 5336, March 10, 1896.

THESE consist in placing just over or on the burner a disc or cap (or both) of metal or other suitable material in such a position as to direct the current of air into the blue portion at the base of the flame. With Argand burners an inner disc is used, and also an outer case turned inwards, so that the inner air column is diverted against the inner surface of the blue zone, the outer air column against the outer surface of the same zone.—L. T. T.

*Air Carburetter, A New System of*. A. Peugeot, Cognigny, France. Eng. Pat. 11,213, June 26, 1896. Claimed under International Convention, April 13, 1896.

SEVERAL forms of an air carburetter intended for supplying hydrocarbon gas engines are shown, each consisting essentially of one or more capillary diaphragms dipping to a constant depth in the liquid hydrocarbon, and through, round, or over which the air to be carburetted is caused to pass. The diaphragms may be cylindrical, vertical, spiral, or of other forms, and are made of such materials as leather wrapped upon wire cloth, ramie, silk, cotton, tannin, piassava, hemp, wadding, felt, ground wood, or fabrics.

—H. S.

*Acetylen, Impts. in the Manufacture of, and in Apparatus therefor*. R. P. Pictet, Geneva. Eng. Pat. 18,207, Aug. 17, 1896.

MANY of the impurities present in acetylene made from calcium carbide are due to the rise of temperature produced by the violent reaction which takes place when the carbide comes in contact with the water, some of the acetylene being partially decomposed. The presence of air in the acetylene is also prejudicial.

The patentee proposes to keep the water used for decomposing the carbide at a temperature of about 20° C. (the limits of - 45° C. and + 60° C. must not be exceeded) by means of a water jacket outside, and coils for circulating water, brine, &c. at any suitable temperature inside the vessel containing the said water. A large bulk of water is used. The carbide of calcium is employed in small pieces, and is so fed into the water by means of hoppers or otherwise, that the adhering film of air is detached by the water (and can escape by the hopper) before the carbide falls into the enclosed portion of the water vessel.—L. T. T.

*Acetylene, Impts. in the Purification of, and in Apparatus therefor*. R. P. Pictet, Geneva. Eng. Pat. 18,208, Aug. 17, 1896.

ACETYLENE made from calcium carbide contains more or less of the following impurities: ammonia, hydrogen, sulphuretted, arseniuretted, and carburetted hydrogen, and carbonic oxide. These are the cause of the acetylene attacking copper and other metals and forming compounds which are dangerous and sometimes detonating, and they also render the acetylene flame less luminous. The present process for removing the detrimental impurities consists in: (1) Bubbling the gas through a concentrated solution of calcium chloride cooled to a temperature between - 20° and - 40° C. (2) Passing the gas through 40 per cent. sulphuric acid at a temperature between - 20° and - 60° C. (3) Washing the gas with a solution of lead salts at the ordinary temperature. (4) Drying the gas over chloride of calcium. "As is well known chemical reactions entirely cease at low temperatures and there is a selective order in which the reactions progressively diminish." The low temperatures are employed to prevent the action of the reagent on the acetylene itself, and are chosen so as to utilise that modifying action of temperature on the reactions. Other reagents may also be used. They are placed in vessels so arranged as to allow of suitable cooling.—L. T. T.

*Heating the Air to be burned in Lamps, Contrivance for*. [*Concentric Chimneys*]. H. Niemeyer, Cassel, Germany. Eng. Pat. 20,552, Sept. 17, 1896.

THE lamps are provided with a concentric arrangement of chimneys, entirely or partly of glass, so that the air for combustion passes first upwards from the outer air, then downwards through an annular channel, and lastly upwards in the central or combustion chamber. By this arrangement the air supply is heated before use. The amount of air can be regulated by the vertical adjustment of the glasses to each other by means of a screw.—R. S.

*Calcium Carbide or Analogous Compounds, Impts. in and relating to, and the Treatment of the same to form a Uniform Composition*. [Tablets.] J. A. Deuther, Boston, U.S.A. Eng. Pat. 20,598, Sept. 17, 1896.

IN practical operation it is found, that the product resulting from the processes now used to produce calcium carbide is

not uniform, and therefore not capable of yielding the same determined amount of gas. In the present invention the calcium carbide is pulverised and thoroughly mixed. It is then treated with a binding material, which may be either a solid or a liquid, and compressed into tablets of a certain weight, so that each tablet represents by decomposition a definite amount of gas.—D. B.

*Carbide of Calcium Protective Coating*, An Improved Process for the Treatment of. M. P. E. Létang, Paris. Eng. Pat. 21,372, Sept. 29, 1896.

To preserve calcium carbide from the influence of moisture of steam, and to dissolve the lime (resulting from the decomposition of the carbide) or to render the same at least "liquid" and thereby to promote its automatic elimination, it is proposed to cover the pieces of carbide with a coating consisting of 55 parts of glucose, 5 parts of petroleum, and 40 parts of carbonate of lime in powder, or similar and effective materials.—D. B.

*A Cetylene Gas, Improved Apparatus for the Automatic Production of*. R. Hadden, London. Eng. Pat. 23,812, Oct. 26, 1896.

In this apparatus for the production of acetylene, the crushed calcium carbide falls in small portions into a vessel of water, this fall being regulated by the rising and falling of the bell of the gas holder, by means of a rod which carries two cross-rods actuating a lever which operates a spring valve in the bottom of the receiver containing the crushed carbide.—L. T. T.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Mesitylene from Acetone*. V. Meyer and W. Molz. Ber. 1896, 29, 2831—2833.

It has recently been shown by Meyer and Pavia that trialkylbenzenes containing the substituents in symmetrical position, take up two acetyl residues when subjected to the Friedel-Crafts reaction (acetylation in presence of aluminium chloride), whilst benzene and its alkyl homologues only take up one acetyl residue when similarly treated. This observation affords a means of ascertaining the constitution of hydrocarbons when only small quantities of material are at disposal. The authors have used it for the purpose of solving the pending question as to the constitution of mesitylene obtained from pure acetone, and confirm their former statement that this "mesitylene" is symmetrical trimethylbenzene. They also disprove the presence of bemellitene in mesitylene prepared from pure acetone, as suggested by Hantzsch.—D. B.

*Naphthas (Natural), Heavy, and their Treatment*. W. Charit-chkow. Chem. Rev. Fett- u. Harz-Ind. 3, 267—269, 286—287.

LARGE quantities of heavy natural naphthas ("goudron naphtha") are found in the North and South Caucasus. As a rule they are rich in bituminous matter, besides containing a large proportion of heavy liquid hydrocarbons. The sample analysed by the author consisted of 85.06 C, 10.54 H, 4.30 O, and 0.01 per cent. of ash. In physical properties, samples from this region agree pretty closely, the sp. gr. ranging from 0.952 to 0.960; viscosity, over 8 minutes (Engler) at 50° C.; flashing point, 135 to 200° C. Very little paraffin is present.

From the fact that the springs are traceable to considerable depths—60 to 200 fathoms—it is believed that we have in these naphthas a separate variety of fluid bitumen, and not an oxidation product of the ordinary light naphthas.

At Geran a spring of heavy naphtha is worked, the refined products comprising a solar oil (sp. gr. 0.88), a valuable cylinder oil (sp. gr. 0.960; viscosity, 900 seconds (Engler) at 50° C.), and various lubricating oils; and the solid pitch residuum (sp. gr. 1.01—1.03) is used for manifold purposes.

The chief difficulty in the manipulation of this naphtha is caused by its considerable hygroscopicity, by the difficulty of

separating water from it, as well as mechanical impurities in suspension. At Geran the crude oil is warmed by the condenser coil from the stills to remove part of the water, the remainder being driven off by heating to 100°—110° C. for 48 hours in the still. Ostrejko's steaming apparatus (this Journal, 1896, 26) should be useful for this class of oils.

In testing such oils in the laboratory, freedom from water and solid impurities is an essential preliminary, and this the author secures by dilution with an equal quantity of petroleum spirit (free from water and completely volatile below 100° C.). After 48 hours' contact, the water and solids are removed by filtration through cotton wool or a dry filter, and the solvent driven off at 100° C. This process is also considered highly suitable for the refinery, the diluent being recoverable, as well as for examining all heavy petroleum products; the flashing-point remains unaffected, provided the petroleum spirit is sufficiently pure.

When some only of the physical properties are to be ascertained, the operation may be shortened, the water being driven off—for flashing-point determinations—by heat at 110° to 120° C. in the Pensky-Martens cup. Specific gravity may be found after solution in a lighter oil of known density, or by direct measurement at a temperature of 50° C., at which the naphtha is sufficiently fluid to allow the instrument to sink freely.

Regarding the question of fractional-distillation testing, the author is not in accord with Wischin as to the necessity for assimilating laboratory practice to that of the refinery, the objects in view being different. Instead of the process of measuring off the distillate by a pipette, which is difficult when steam distillation is performed, he prefers to provide the still with a float and index, thus allowing the volume to be read off direct. It is advisable to terminate the operation as soon as the residue has become solid and of a density greater than 1, and as many equal volumes of fractions as possible should be obtained.—C. S.

*Wood, Treatment of, with Antiseptics prepared from Petroleum*. A. W. Adiasiewitsch. Trudy. bak. otd. imp. russk. Tech. obschtsch. 1896, 11, 243.

See under IX., page 45.

### PATENTS.

*Petroleum, Crude, and Analogous Oils; Impts. in and Apparatus for Refining, by means of Fuming Sulphuric Acid*. J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen. Eng. Pat. 23,436, Dec. 6, 1895.

RECENTLY unsuccessful attempts have been made to use fuming sulphuric acid for the purification of petroleum. One cause of failure is due, with some oils, to the difficulty of securing an intimate admixture with the oil, of the fuming sulphuric acid, as the latter, immediately after contact, rapidly forms pitch-like bodies possessing an inner nucleus of unaltered acid, which either takes no part in the purification, or only acts after prolonged agitation. The principle of the process for overcoming this difficulty consists in mixing in the fuming sulphuric acid at the point of contact of streams of the crude oil (or streams of air and oil), the streams possessing a different velocity, so that considerable friction occurs, whereby the acid is in a sense "rubbed or ground" into a fine state of division and becomes most intimately admixed with the entire body of the oil. Another cause of failure is the fact that when treating some crude oils, especially the heavier fractions, with sulphuric anhydride, besides the ordinary pitch-like compound, which separates out, other similar combinations are formed in some cases, which do not separate from the oil. On washing such oils in the usual way with water and alkali, the impurities are regenerated and impart a dark colour and objectionable odour to the product. The said combinations can by this invention be readily removed by treatment of the oil with a small percentage of ordinary concentrated sulphuric acid. The refined oil obtained by working according to this invention is said to be lighter in colour than that obtained when using either concentrated sulphuric acid alone, or sulphuric anhydride alone, and on exposure to light it continuously becomes

lighter in colour, whilst the product purified with ordinary concentrated acid alone, bleaches a little at first, but afterwards re-assumes a yellow colour. The loss of oil is also said to be less. About half the quantity of acid hitherto employed is used. Sulphuric acid containing the following percentages of anhydride or  $\text{SO}_3$  have been found to give good results:—With benzene 20 to 60 per cent. of  $\text{SO}_3$ , with petroleum 10 to 20 per cent., with lubricating oil 5 to 20 per cent., and with vaseline 25 to 30 per cent. of  $\text{SO}_3$ .—D. B.

*Meters [Distillery] for Measuring Spirits and Distillates, Impts. in.* C. F. Chapp, Basse Terre, Guadeloupe. Eng. Pat. 23,849, Dec. 12, 1895.

See under I., page 33.

#### IV.—COLOURING MATTERS AND DYES.

*Patent Blue Dyestuffs, Researches on. Part I. Derivatives of Benzylsulfone, Benzylsulfate, and Benzalsulfone.* P. Fritsch. Ber. 1896, 29, 2290—2301.

The constitution of the leuco-sulphonic acids of the Patent Blue dyestuffs is probably—

As evidence in support of this, in regard to the positions occupied by the sulphonic acid groups, may be adduced the ease with which *m*-hydroxy- and alkoxy-tetra-alkyldiamidotriphenylmethane compounds are sulphonated at the ordinary temperature, as compared with, for instance, tetramethyldiamidodiphenylmethane, for the sulphonation of which with monohydrated sulphuric acid, a temperature of  $110^\circ \text{C}$ . is required. From this it would appear, *first*, that the entrance of a sulphonic acid group into the molecule of the leuco-base of a Patent Blue dyestuff, is favourably influenced by the presence in the molecule of a hydroxyl- or alkoxy-group, and, *secondly*, that the hydroxybenzene residue is itself attacked by the sulphuric acid in preference to the aniline residues. Such being the case, it follows, according to the law of substitution, that the ortho- and para-positions relative to the hydroxyl- or alkoxy group are those which are taken up by the sulphonic acid groups.

The circumstance that the dyestuffs of the Patent Blue class possess a green-blue or blue colour may be explained by assuming that the sulphonic acid group, which is in the position ortho to the central carbon atom, has a potent colouring influence. Thus, blue dyestuffs are formed by condensing tetramethyldiamidodiphenylcarbinol with (1) *m*-amidobenzene sulphonic acid (Ger. Pat. 65,017) and subsequently eliminating the amido-group and oxidising, and with (2) *m*-toluenesulphonic acid (Ger. Pat. 80,982), and oxidising the resulting product.

As the blue colour of the aqueous solutions of the dyestuffs in question is not affected by caustic soda in the cold, or by sodium carbonate or ammonia at the boil, it is probable that the sulphonic acid group is in the molecule in the condition of an anhydride of the type—

The first of these formulae being considered the more probable, attempts are being made to prepare the dyestuffs from the anhydrides—

or their derivatives.—E. B.

*Cutch, The Preparation of.* Indian Pharmacologist, 1896, 1, 88.

The trees are regarded as mature when about a foot in diameter; they are then felled and cut into blocks two or three feet long. Trees between 25 and 30 years old are regarded as the most suitable. The bark and outer sapwood are generally removed and rejected, the red heartwood is then cut into chips; the branches are utilised in some districts, in others not. The chips are boiled in water for 12 hours; when the water is reduced to one-half, the chips are removed and the liquid boiled down in iron pans, with stirring, until it becomes syrupy; the stirring is continued during cooling until the mass is cold enough to be handled, when it is taken out and spread on leaves in a wooden mould or frame, and left over night. The details of the boiling and evaporating processes vary considerably in different regions; from the widespread conviction of the necessity for stirring or beating the concentrated solution, it might be inferred that an oxidation process is thereby effected. In Baroda the liquid is repeatedly wrung from a blanket and allowed to fall in drops from as great a height as possible. One ton of timber in the round may be taken as yielding 250 to 300 lb. of cutch.—A. C. W.

*Madder Colouring Matters, History of.* C. Liebermann and S. Friedländer. Ber. 1896, 29, 2851—2854.

Owing to the difficulty experienced in the isolation of the different constituents present in the colouring matters derived from the madder root, their chemical constitution has for a long time been the subject of much speculation. Runge, in his prize essay on madder and its dyes, published in 1835, expressed a doubt as to the purity of Robiquet and Colin's alizarin discovered in 1826, and of the so-called *matière colorante rose* (presumably purpurin) described by Gaultier de Claubry and Persoz about the same time. As pure substances Runge mentioned two colouring matters, which he called madder red and madder purple, and from his description of their distinctive properties it is evident that they correspond with the alizarin and purpurin of the present day. The authors have recently had occasion to examine some of the dyed specimens prepared by Runge for the above work. In most cases the tents contained mixtures of both colouring matters. Almost pure purpurin was detected in several patterns, but these were marked madder red. Pure alizarin could not be obtained from any of the specimens, although one marked madder purple was found to be very rich in alizarin. Having found alizarin to predominate in the Turkey-red patterns prepared about 50 years ago by Persoz for his work, entitled "*Impression des Tissus*," the authors are satisfied that in Runge's specimens the alizarin could not have been oxidised to purpurin. They conclude that although from the description of the distinctive properties of alizarin (madder red) and purpurin (madder purple) it is evident that Runge successfully isolated the two colours on a small scale, their separation in large quantities could not have been effected with the same degree of accuracy. The raw material he had at his disposal being rich in purpurin, the separation with alum followed by Runge could scarcely give satisfactory results even under the most favourable conditions.—D. B.

*o- and p-Nitrophenol and their Technical Uses.* [Preparing Phenacetin.] L. Paul. Zeits. für ang. Chem. 1896, 587.

See under XX., page 62.

#### PATENTS.

*New Azo Colouring Matters [Cotton Browns and Reds], The Manufacture or Production of.* J. Leviustein and Leviustein, Ltd., Manchester. Eng. Pat. 23,523, Dec. 9, 1895.

DYESTUFFS said to surpass in fastness to light most of the azo colours hitherto known, are produced according to this specification, from the mixed tetrazo colouring matters obtained by combining equimolecular proportions of a tetrazotised *p*-diamine, salicylic acid, or one of its homologues, and aniline, or one of its homologues. The colouring matter so formed is then further diazotised and combined with a naphthylamine, naphthol, amidonaphthol, or

dihydroxynaphthalene sulphonic acid, or with a corresponding compound in the benzene series. Thus the tetrazo solution from 18.4 kilos. of benzidine, is combined with 14 kilos. of salicylic acid, and the intermediate compound formed, is run into a solution of 26 kilos. of aniline hydrochloride. After stirring for about 12 hours and heating for another six hours to about 40–50° C., the mixture is made alkaline and the excess of aniline removed. The yellow dyestuff having the formula—

is acidulated with hydrochloric acid, diazotised with 7.2 kilos. of sodium nitrite, stirred for a few hours, and after standing for about 12 hours, the brown diazo compound formed is added with constant stirring to an alkaline solution containing 24 kilos. of 7-amidonaphthol sulphonic acid. The formation of the dyestuff is completed within a short time, when it is salted out, filter-pressed, and dried. It forms a brownish-black powder, which dyes unmordanted cotton a deep brown. The shades vary from red to deep brown by employing other *p*-diamines in place of benzidine, such as tolidine, diaminidine, ethoxybenzidine, or diamido-tolbene disulphonic acid, and also by substituting *o*-toluidine or *p*-xylylene for the aniline. Moreover, these dyestuffs are suitable, not only for cotton, but also for wool, silk, jute, or other textile fibres.—T. A. L.

*Para-nitrophenol and Ortho-nitrotoluene-para-sulphonic Acid, Impts. in the Production of.* G. B. Ellis, London. From "La Société Chimique des Usines du Rhone, anct. G. P. Monnet et Cantier," Lyons, France. Eng. Pat. 24,193, Dec. 17, 1895.

THE direct nitration of phenol always yields a mixture of *o*- and *p*-nitrophenol, together with a certain proportion of tarry matter. In the present invention, phenol is first condensed with an aromatic sulphonic chloride in presence of an alkali, and the ester thus obtained yields directly, without tarry products, a dinitro derivative, which, on hydrolysis with an aqueous solution of a caustic alkali, forms the *p*-nitrophenolate of the alkali together with the alkali salt of *o*-nitrotoluene-*p*-sulphonic acid.

The further nitration of the ester yields a product which is easily saponified even at the temperature of the water-bath, and with caustic alkalis in very dilute solution. *p*-Toluenesulphonic chloride is particularly specified, since it is produced in large quantities as a by-product. The following example gives the method and the quantities employed:—Sodium phenolate is dissolved in five times its weight of water at 80° C., and mixed with the theoretical quantity of *p*-toluene sulphonic chloride with constant agitation. The ester may also be prepared by dissolving 100 kilos. of phenol and 42 kilos. of caustic soda in 1,000 litres of water by means of a steam jet and gradually adding 210 kilos. of *p*-toluene sulphonic chloride. When the mixture no longer smells of this latter, it is cooled, the ester filtered off, washed, and dried. It has the formula—

and melts at about 95° C. In order to nitrate it, a finely ground mixture of 100 kilos. of the ester with the same weight of potassium nitrate is gradually added to 1,000 kilos. of sulphuric acid (66° B.) at a temperature below 15° C. The nitro product is then separated, well washed, dried, and recrystallised from benzene, when it melts at 115° C. It has the formula—

The hydrolysis may be performed by suspending and heating the dinitro ester in its own weight of caustic soda (36° B.). On cooling, sodium *p*-nitrophenolate crystallises out, and *o*-nitrotoluene-*p*-sulphonic acid may be precipitated from the mother-liquor by dilute mineral acids. Other esters described in the patent are: benzene sulphonic phenol ester melts at 35° C. and gives a dinitro ester melting at 133° C.; the phenol ester of *o*-toluene sulphonic acid melts at 52° C. and yields a nitration product melting at 195° C., which on hydrolysis decomposes into *p*-nitrophenol and *p*-nitro-*o*-toluene sulphonic acid (1.4.2) $\text{C}_6\text{H}_3 \cdot (\text{CH}_3)(\text{NO}_2)(\text{SO}_3\text{H})$ ; the phenol ester of *o*-naphthalene sulphonic acid melts at 75°, and gives a

nitration product which on hydrolysis yields *p*-nitrophenol and several nitro-*o*-naphthalene sulphonic acids are obtained. In a similar manner *β*-naphthalene sulphonic chloride gives a phenol ester which melts at 99° C. and yields on nitration and hydrolysis, *p*-nitrophenol together with different nitrated derivatives of *β*-naphthalene sulphonic acid.—T. A. L.

*Stable Double Salts of Chloride of Zinc and the Diazo or Tetrazo Compounds respectively of Amido-azo and Diamido-azo Compounds, Manufacture of.* Farbwerke vorm. Meister, Lucius, and Brüning, Hoechst-am-Main, Germany. Eng. Pat. 1645, Jan. 23, 1896.

THIS patent claims the manufacture of the stable double salts of zinc chloride with the diazo or tetrazo compounds of amido-azo or diamido-azo bodies respectively, by precipitating with zinc chloride solution, the filtered aqueous solutions obtained by diazotising the base.—A. C. W.

*Direct-dyeing Azo Colouring Matters [Cotton Blacks], Manufacture of.* C. D. Abel, London. From "The Actien Gesellschaft für Anilin Fabrikation," Berlin, Germany. Eng. Pat. 2196, Jan. 30, 1896.

THIS specification is an extension of Eng. Pats. 4018, 7969, and 9431 of 1895 (this Journal, 1896, 110 and 270). The dyestuffs are produced by combining with amines, phenols, and amidophenols, the tetrazo derivatives of compounds of the following general formula—

where X and Y represent amido or hydroxyl groups and Z a radicle containing a diazotisable amido group. For instance, 18.8 kilos. of the compound—

obtained from amidonaphthol disulphonic acid  $\text{H}_2$ , nitro-amidodiphenylamine sulphonic acid, and *p*-nitraniline, are tetrazotised by means of hydrochloric acid and 3.5 kilos. of sodium nitrite. The tetrazo compound is run into a solution of 6.1 kilos. of *m*-tolylene diamine kept alkaline by means of sodium carbonate. The dyestuff separates as a black precipitate, and, after stirring and heating, it is filtered off and dried. It is readily soluble in water, and dyes unmordanted cotton a greenish-black. By employing an equivalent amount of *β*-naphthol in place of the *m*-tolylene diamine, a bluish-black dyestuff for cotton is produced.—T. A. L.

*Blue Colouring Matters [Gallocyanines], The Production of.* W. H. Claus and A. Rée, Droylsden, Manchester. Eng. Pat. 2705, Feb. 6, 1896.

THE aniline addition product of gallocyanine (which is obtained by the action of nitrosodimethylaniline hydrochloride on gallic acid) yields, when sulphonated, useful bright blue dyestuffs, which have a great affinity for mordants, and can be employed for dyeing wool and for calico printing. Finely ground gallocyanine is mixed with four times its weight of aniline and allowed to stand for several hours, when the excess of aniline is removed by washing with benzene or spirit. The condensation product, after filter-pressing and drying, is sulphonated with 4 parts of sulphuric acid at about 70° C. The melt is then poured into water, when the colouring matter precipitates, and, after filtering off, it is well washed, treated with ammonia or an alkali, and evaporated to dryness. Another method employed for obtaining the condensation product in a form suitable for dyeing is to mix 20 kilos. of it with 180 litres of water, 4 kilos. of strong ammonia, and 3 kilos. of sodium bisulphite, 60° Tw. The shades obtained are much bluer than those produced with gallocyanine itself. The condensation may also be performed in spirit solution and the product thus obtained, or as above, after dissolving in sulphuric acid, pouring into water, and washing free from acid, separates as a very fine paste, which may be employed in calico printing. (See also Eng. Pat. 1890, 569; this Journal 1891, 131.)—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

## PATENTS.

*Cleansing and Recovering Grease and Oil from Cotton and other Waste and Wool, A Method of and Apparatus for.* G. E. Wright, Nottingham, and W. Monk, Nottingham. Eng. Pat. 22,183, Nov. 21, 1895.

The method consists of circulating three charges of liquid solvent through the material, the solvent being pressed out each time and collected. On evaporating the latter, the oil remains behind, whilst the volatile liquid may be condensed and used over again. The washed cotton waste or wool is dried by passing hot air through the vessel containing it.

The essential features of the apparatus are a press fitted with two rams, one fixed and hollow, and suitable connections to a circulating pump and supply tank containing the liquid solvent. Evaporating pans, condensers, a fan, air-heater, and vacuum pump also form part of the apparatus.

The advantages claimed for this apparatus are, the combination of the fixed hollow ram of the press (which is in communication with the solvent supply tank, air heater, &c.) with a movable ram connected to the movable press bottom, which in turn is in communication with the solvent collecting tanks, and also the arrangement of suspended perforated platforms or horizontal chains for loosening the material, to expedite the operation of drying.—W. P. S.

*Degreasing and Cleansing Wool, Cotton Waste, and like Fibrous Material: Impts. in Apparatus for.* F. N. Turvey, Nottingham. Eng. Pat. 1370, Jan. 20, 1896.

The material is passed in the form of a sheet or layer into the cleansing chamber by means of an elevator or endless lifting chain. The levelling apparatus is situated in an airtight chamber between an air-lock and the degreasing apparatus. This latter consists of a combination of beaters carried in a shogging frame together with an arrangement of rakes and rocking forks for beating the material and advancing it through a series of shallow solvent tanks in the degreasing chamber. The heating of the material takes place upon perforated supports or trays having upwardly curved ends for directing it towards the squeezing rolls, by which it is pressed almost dry on leaving the machine. A second elevator raises the material to these rollers. Suitable means are provided for regulating the feed and thickness of the layer as it passes into the degreasing chamber. After leaving the squeezing rolls, the material falls into a drying chamber.—W. P. S.

## VI.—DYEING, CALICO PRINTING, PAPER-STAINING, AND BLEACHING.

*Wool, After-Treatment of Chlorinated.* Glad and Co., Langensalza, Thuringia. Textile Colorist (U.S.), 18, [215], 336.

Wool which has been chlorinated, for the purpose of giving it a silky lustre and feel, contracts a yellowish tint, which renders it unsuitable for being dyed very delicate colours. To remove this yellow tint the authors have devised the following process:—The well-washed wool is passed through a weak bath of hydrochloric acid, drained, and treated for about 20 minutes in a cold solution of sodium thiosulphate of  $\frac{1}{2}$  B., and rinsed in water slightly acidified with HCl. By this treatment the silky appearance and feel of the wool are promoted, but at the same time a strong yellowish tint. This may be removed by passing the wool through a reducing bath, which is made up as follows:—For 25 kilos. of wool take 800 litres of water at 40°–50° C., 2 kilos. of stannous chloride, and 4 litres of hydrochloric acid of 30 per cent. strength. From this bath the wool is again rinsed in acidulated water.—I. S.

*Scouring of Woollen, Worsted, and Mohair Yarn.* L. K. Frankel and A. Hamburger. Textile Colorist (U.S.), 18, [215], 326.

The authors emphasise the necessity of removing every trace of oil from the yarns which they receive during the spinning process, prior to their being dyed, since otherwise the colours are liable to be cloudy, or the yarn may be stained. If lard or olive oil only has been used, the scouring is a simple matter. But the process is one of considerable difficulty if mineral oils, or a compound containing mineral oil, have been employed. Such compounds are generally used for coarse and cheap carpet yarns. The authors are of opinion that even for the coarsest yarns, only such oils should be used as are readily removable, since the saving in labour and soap would compensate for any difference in cost, whilst leaving the fibre in a better condition.

As the most suitable detergent, the authors recommend potash soaps made from olive oil, or olive-oil foots, and potassium carbonate, mixed in the proportion of 75 per cent. of the former to 25 per cent. of the latter. The quantity to be used will depend on the amount of fatty matter present in the yarn. For coarser yarns good palm-oil soap, with sufficient sodium carbonate or soda ash, "will be found to answer all the requirements of the carpet manufacturer"; but for woollen and worsted yarns used in finer carpets, potash soap and potassium carbonate are to be preferred.

Excessive heat of the scouring bath is to be avoided, as too high a temperature may cause the yarns to felt and render them harsh as well as "lean" in appearance. The temperature should be below 125° F.; for fine yarns, 115°–120° F., which may be increased to 130° F. in case mineral oil is present.—I. S.

*Scouring and Finishing Woollen, Worsted, and Mohair Piece Goods.* L. K. Frankel and A. Hamburger. Textile Colorist (U.S.), 18, [215], 326–327.

On the thorough cleansing of the piece before dyeing depends its finish and beauty. Soaps used for the scouring and felling of woollen goods should therefore be free from alkaline silicates, which communicate a harsh feel; and from rosin, which causes cloudiness and makes the pieces sticky and ill-smelling. The authors prefer palm-oil to tallow soaps, because tallow contains a large proportion of stearin, the soap of which is not so soluble as that from palmitin or olein. Solubility of the soap is an important feature, so that it can be easily washed out. Tallow oil, that is the liquid constituents of tallow, in combination with palm oil, "makes an ideal fulling soap." The soap should be nearly neutral, as an excess of caustic alkali will corrode the fibre and render the goods harsh. To remove any fatty matter from the pieces, sodium or potassium carbonate may be added to the soap-bath, the authors giving preference to the latter.

For worsted goods, where thorough cleanliness and softness of finish is more desired than a felted surface, olive-oil potash soap, or a mixture of equal parts of olive-oil potash and olive-oil soda soaps will yield satisfactory results, giving the pieces a soft, smooth finish and a clear, bright colour.

Mohair and lustre fabrics attain their highest brilliancy, it is alleged, when scoured with a mixture of olive-oil potash soap and potassium carbonate.—I. S.

*Tartar Emetic or Antimony Fluoride Salts?* E. Eulenthaler, Leipziger Farber- u. Zeugdrucker Zeit., 45, 491–492; and R. Erhardt, the same Journal, 45, 515–518.

CERTAIN manufacturers of "antimony fluoride salt" having claimed that by the use of this product instead of tartar emetic a saving in cost of 52 per cent. may be effected, E. Eulenthaler has tested this statement on the large scale, and is unable to confirm it. He finds, on the contrary, that amounts of the two substances containing an equal weight of  $\text{Sb}_2\text{O}_3$ , do not give equally good results, and that even when the same amount of each substance is used, a larger quantity of dyestuff is required when the fluoride is employed, than with tartar emetic, to obtain an equal depth of shade. This he attributes to the readiness with which

the fluoride suffers decomposition, free acid being liberated, which dissolves tannate of antimony from the fibre. The alleged saving in cost is due to the fact that dyers are in the habit of using far too large an amount of tartar emetic in the fixing bath.

In a reply to the above, R. Erhardt states that his experience fully substantiates the claims of the manufacturers; he finds the necessary amount of fluoride salt to be only half that of the tartar emetic usually employed, and the saving in cost amounts to 56 per cent. or more. The ready decomposition of the fluoride causes a much greater fixation of  $Sb_2O_3$  on the fibre—in fact, the bath is perfectly exhausted, and the acid liberated is no more injurious than the tartaric acid from tartar emetic; however, in both cases, a thorough washing should follow the fixing operation. It is true that the amount of antimony compound employed, and also the quantity of tannin, is frequently too great, but the necessary amounts vary according to the colouring matter, and unless they are separately ascertained for each dyestuff, it is well to use quantities known to be sufficient.—R. B. B.

*Cotton Cloth, The Drying of Mordanted.* M. J. Włucki. Zap. imp. russk. techn. obschch. 1896, 30, [6—7], 231.

If cloth impregnated with a tannin solution be dried on hot cylinders before passing it through the antimony solution, then the cloth will dye darker shades on one side than on the other, the side which first touches the hot cylinders eventually acquiring the darker shade. The difference is also the greater, the hotter the cylinders are. The colour will also be uneven, since knots, thicker threads, and in general all those parts which are pressed more firmly against the hot cylinders, will dye darker than the other parts. The cause of this is that where the cloth comes into contact with the hot cylinders, the solvent of the tannin is evaporated, and fresh moisture from the interior of the cloth is drawn by capillary action towards the partially dried surface, causing thereby a local accumulation of tannin. The author is of opinion that this tendency of the mordant to accumulate on the surface of the cloth during drying, might be utilised to effect a saving in mordanting and colouring materials, by so conducting the drying that only one side of the cloth shall touch the cylinders, and never the other. To ensure evenness, the temperature of the cylinders should be so regulated that the cloth shall be barely dry when leaving them.—I. S.

*The Dyeing of Hard-milled Woollen Felts.* W. Ringmann. Färber Zeit. 7, 457.

The method of dyeing felt, 10—15 millimetres in thickness, depends upon the nature of the previous milling process. Goods which have been milled with soap are boiled for two hours with 10 per cent. of sodium sulphate only, half the necessary quantity of dyestuff is then added, together with 5 per cent. of sodium bisulphate, and after boiling for 1—1½ hours longer, the remainder of the dyestuff and another 5 per cent. of  $NaHSO_4$  are added. When dyeing in old liquors the acid must be neutralised with soda before proceeding as above.

If the goods have been milled with acid, the acid remaining in the fibre is first neutralised by boiling for two hours with soda and a little sodium sulphate, after which dyeing proceeds as before.

In the case of felt 5—8 mm. thick, it is sufficient to neutralise, boil ½ hour with dyestuff only, add the acid, and continue boiling.

Piano felts 10—20 mm. thick, which require to be perfectly dyed through, are half milled with soap, dyed as given above for thick felts, and the milling is then completed with acid and hot water.—R. B. B.

*Stannous Chloride, Preparation of. [Recovery of Tin from Spent Tin Baths.]* L. Vignon. Textile Colorist (U.S.), 18, [215], 331.

See under VII., page 43.

## PATENTS.

*Waterproof Fabrics, Impts. in the Printing of, and Apparatus therefor.* J. Berry, Salford. Eng. Pat. 1375, Jan. 20, 1896.

THE inventor has found that by spreading a film of water on rubber, or the proofed surfaces of waterproof fabrics, before entering the printing machine, such goods can be printed on without the application of farina or other finely powdered material to the surface. To carry out the process, two (or more) troughs are placed in front of the printing machine, each being provided with one or more rollers, over which the fabric travels before entering the printing machine. One only of the troughs contains water into which the revolving rollers dip, whilst the other is empty, its rollers serving the purpose of removing excess of moisture.—I. S.

*Dyeing [Felt or Cloth], An Improved Method of.* A. H. Brownlow and J. Stansfield, Leeds. Eng. Pat. 2844, Feb. 7, 1896.

THE improvement consists in dyeing thin felt or cloth a different shade on each side. The cloth is first dyed through any required shade of colour and finished in the usual way; a second dyestuff is then applied to one side of the cloth only on a printing machine "of any suitable construction." —I. S.

## VII.—ACIDS, ALKALIS, AND SALTS.

*Sulphur, Extraction of, from Brimstone Earths.* E. F. White. Eng. and Mining J. 62, [23], 1896, 536.

THE author deals with the "efficiency of apparatus" and the "economy of method" of a new steam separator for the production of crude sulphur. "Efficiency" he defines as the ratio expressed by  $\frac{\text{available product}}{\text{total expenditure}}$ , the two factors being developed in like terms.

"Economy of method" varies with the costs of labour, fuel, and water, and in some cases is attained without high "efficiency." Some Sicilian deposits, containing 20 per cent. of S, are more economically worked by simple methods, possessing an efficiency of only 40 per cent., than by apparatus yielding a much larger return. The purer sulphur obtained by distillation is never obtained direct from the natural earths. It is found much more economical to subject crude sulphur alone to distillation. The older forms of steam-heat separators used for the production of this crude sulphur, were wasteful of heat and inconvenient in manipulation. The separator described by the author possesses advantage in these respects. It is designed for use with water, steam, or air as heating media. A conical vessel, in shape resembling a blast furnace, is provided with a double outside casing. Two annular spaces are thus formed round the body of the apparatus. The sulphur earth in 3-in. lumps is fed continuously from the top into the middle annular space, whilst hot water or steam, from a boiler working under 80 lbs. pressure, is admitted to the outer annular space and to the inner cone. The sulphur in the earth, during its passage downwards between the two heating surfaces is melted, and is collected in, and automatically drawn off, from a steam-jacketed receiving-pan fixed beneath the cone. Mechanical arrangements keep the earth travelling downwards in the annular space, and remove the residual earth continuously from the draining plate and from the bottom of the receiving pan. The cost of treating sulphur earth by this apparatus at the mines on a scale of 25,000 tons of crude sulphur annually, with separators of a capacity of 20 tons of earth per 24 hours, is 7s. 3d. per ton. For a 65 per cent. earth, this works out to 11s. 2d. per ton of crude sulphur. Since the specific heat of sulphur and of the earths usually allied with it are nearly the same, and since the latent heat of fusion of sulphur is exceedingly small, the cost of treatment per ton of crude sulphur for poorer earths, can safely be calculated from these costs for earth containing 65 per cent. of sulphur.

—J. B. C. K.

*Hydrochloric Acid free from Arsenic, Preparation of.*  
G. Friese. *Chem. Ind.* 1896, **19**, 187.

Hydrochloric acid perfectly free from arsenic is prepared in the usual way from common salt and commercial sulphuric acid, except that the gas, before passing into the absorption apparatus, is washed, and remains in contact with boiling water or steam. The volatile arsenic chloride, which is carried over with the hydrochloric acid, reacts with the water, forming arsenious acid, which is not volatile, and hydrochloric acid. The wash-water must be kept boiling, as at a certain point of concentration of the acid solution formed, a re-conversion of the arsenious acid into volatile arsenic chloride takes place. After a long time, the wash-water will have become so charged with arsenic, that the hydrochloric acid carries over some arsenic trichloride with it. When this point has been reached, the wash-water must be renewed.

The hydrochloric acid obtained by this method, is so completely free from arsenic that it remains absolutely clear on warming with tin, but the author is uncertain whether the method will work as well on a large scale as on the laboratory scale.—A. S.

*Fusibility, Abnormal: of Mixture of Alkaline with other Sulphates.* Le Chatelier. *Comptes rend.* 1896, **123**, [19], 746—749.

The author finds, in opposition to the general rule, that the melting point of alkaline sulphates is elevated by an admixture of other metallic sulphates. Accompanying the paper is a set of curves which exhibit the influence on the melting point of sodium sulphate, of progressively increased admixtures of calcium sulphate, magnesium sulphate, &c., respectively. It appears that the melting point does not increase indefinitely as the proportion of added sulphate becomes more elevated, but attains a maximum at concentrations (above which the curve again descends) varying in the different examples. The increase is greatest in the case of  $\text{CaSO}_4$ , barely noticeable with  $\text{MgSO}_4$ , whilst  $\text{BaSO}_4$ ,  $\text{CdSO}_4$ , and  $\text{PbSO}_4$  occupy an intermediate position. Apart from this, the formation of double salts, such as  $\text{PbSO}_4 + \text{Na}_2\text{SO}_4$ ,  $2\text{MgSO}_4 + \text{Na}_2\text{SO}_4$ , and  $2\text{CdSO}_4 + \text{Na}_2\text{SO}_4$  is indicated by distinct breaks at corresponding points in the complete curves. In addition, it was observed that  $\text{Na}_2\text{SO}_4$  and all its mixtures (within certain limits) with  $\text{CaSO}_4$  or  $\text{PbSO}_4$ , after fusion, remain perfectly transparent, even when cooled to atmospheric temperature, and exhibit identical crystalline structure. It is concluded, therefore, that  $\text{Na}_2\text{SO}_4$  is isomorphous with some of its own double salts.—H. T. P.

*Stannous Chloride, Preparation of.* [Recovery of Tin from Spent Tin Baths.] L. Vignon, Textile Colorist (U.S.), **18**, [215], 334.

THE author has found that by treating the oxides of tin with hydrochloric acid, in the presence of metallic tin, they may be converted into stannous chloride, the reactions being—

The process is utilised for the recovery of tin from old tin baths, or the waste liquors of the dyehouse containing tin in solution. From such waste solutions the tin is precipitated as  $\text{SnO}$  or  $\text{SnO}_2$  by means of lime, sodium carbonate, sulphuric acid, sodium sulphate, &c. The oxides are digested in concentrated hydrochloric acid, and, if necessary, heated to  $80^\circ\text{C}$ . until solution is complete, and the meta-stannic acid which it may contain, is transformed into stannic acid. This hydrochloric acid solution is then treated with granulated tin, which dissolves without evolution of gas. The solution is then concentrated, and the stannous chloride allowed to crystallise.—I. S.

*Borax, Commercial, Valuation of.* G. Heid. *Zeits für angew. Chem.* 1896, 679.

See under XXIII., page 66.

# PATENT.

*Caustic Soda, Carbonate of Soda, and Sulphide of Sodium [as By-products], Impts. in the Manufacture of.* H. R. Angel, London. Eng. Pat. 335, Jan. 6, 1896.

To obtain caustic soda and carbonate of soda, sulphate of soda is mixed with iron oxide, coal, or coke, and with roasted or unroasted lime, blende or other ores. During the process of smelting, the sulphate of soda is changed into sulphide and this is converted into caustic soda by the iron oxide. A portion of the charge is converted into carbonate of soda and a portion remains as sulphide if unroasted ores be used; if, however, the ores have been well roasted before treatment, this sulphide entirely disappears, and a solution is left of a strength such that it contains about 75 per cent. of caustic soda and 25 per cent. of carbonate of soda. The claim is for the "Recovery of caustic soda, carbonate of soda, and sulphide of sodium as by-products, from the reduction of refractory and other ores."—D. B.

## VIII.—GLASS, POTTERY, ENAMELS.

*Glass-Making, Aluminium in.* Central-Blatt, f. Glas-Ind. **11**, 284.

According to L. Appert the employment of aluminium in glass-making is calculated to revolutionise the industry. From the results of numerous analyses of old window-glasses he is convinced that aluminium will increase the durability and elasticity of the product. Appert has found that 7 or 8 per cent. of this metal can easily be added to molten glass. The fusibility of the glass thus becomes increased, without any sensible loss of ductility. Impure aluminium colours the glass, through presence of traces of iron, but this should not be difficult to remedy.—C. S.

*Glass, Proportions of Constituents in the Mass.* R. Hohlbaum. *Sprechsaal*, **29**, 1170.

FREQUENTLY the defects in glass are due to wrong proportions of the materials having been taken. The simplest way of detecting errors of this class is to calculate out the composition of normal glass from pure materials to the materials at disposal, and compare the resulting proportions with those taken. For this purpose, taking normal soda-lime glass as a basis, the amount of silica is calculated according to Benrath's formula  $z = 3(x + y)$ , wherein  $x$  = alkali oxide,  $y$  = calcium oxide, and  $z$  = silica; and since  $x = 62$  parts of  $\text{Na}_2\text{O}$  and  $y = 56$  parts of  $\text{CaO}$ , then 354 parts of silica are required. The above amounts of  $\text{Na}_2\text{O}$  and  $\text{CaO}$  corresponding to 142 and 100 parts of chemically pure Glauber salt and chalk respectively, the following proportions result for the mixture (normal glass):—Sand, 354 parts; Glauber salt, 142 parts; chalk, 100 parts; and coke, 9 parts.

In practice it is found that the coke should not exceed 5 to 6 per cent. of the weight of Glauber salt, the carbon monoxide evolved during the reduction also assisting therein.

If now the materials at hand are: Sand, 99 per cent. pure; Glauber salt, 96 per cent. pure; and chalk, 98 per cent. pure, then the proportions must be modified from the foregoing, as follows:—

Sand.	Glauber Salt.	Chalk.	Coke.
358	148	102	9
or per 100 parts of sand	11	28	2.5

When the Glauber salt is replaced by sodium carbonate the calculation is similar, the weight of the molecule (106) being taken; but in this case the coke may be omitted.

—C. S.

*Earthenware Industry, Impts. in the.* H. Hecht. *Dingler's polyt. J.*, **302**, [10], 237—240.

THE composition of Thuringian porcelain body is given in *Sprechsaal*, **28**, 59, 88; *Illus. Fachbl. f. Glas- Porzell. u.*

Steingrund, 3, 282. It appears that English and Bohemian earthenware are used along with the German raw materials, particularly for ware that is designed to have a fine appearance, some makers also importing earth and "body" from France.

According to M. Hosoki (Thonind. Zeit., 19, 349) *Imari porcelain* (Japan) is prepared from a natural porcelain earth, resembling that found in some parts of China, which needs no addition of quartz or feldspar, but can be worked up direct. This earth, "Idzumiama," consists of 49.07 per cent. of clay, 14.52 of quartz, and 36.61 of feldspar, and is nearly allied in composition to hard German porcelain. By the addition of a certain proportion of wood ashes the earth is converted into a suitable glaze. The ordinary firing temperature is employed in the kilns.

In the *modelling of porcelain ware* the tendency is to discard turning in favour of moulding, the increased mobility necessary in the mass being obtained by additions of sodium carbonate or other alkali in flux. This action of the alkali is explained by Kosmann (Thonind. Zeit., 19, 32) by the assumption that the clay has a stronger affinity for the water of hydration in the alkali, which it displaces, the heat thereby generated increasing the fluidity of the mass. Moreover, soda, though inactive towards alumina, may dissolve some of the interstitial particles of silica, and so dilute the mass and increase its mobility. On the other hand, A. Zebisch (Sprechsall, 27, 1005, 1895) considers the amount of soda too small for its action to be thus explained, and attributes the effects rather to osmosis. Seger (Gesammelte Schriften, p. 573) assigns the action of alkalis, and the converse effect of acids, to molecular alterations, and attributes the plasticity attained by porcelain earth in "rotting" to a putrescent bacterial fermentation of the organic matter in the water, acid compounds, which increase the pliability of the mass, being formed.

The *cracking of the glaze on ceramic ware* is explained by Le Chatelier (Monit. céram., 26, 162) as being due to the irregular expansion of the sand when heated. His experiments showed that all siliceous substances, including the amorphous silica present in ceramic earth, undergo sudden alterations in volume at certain temperatures, their expansion thus contrasting with that of the glaze, which is regular. The fact that porcelain alone expands regularly is ascribed to the probable conversion of its silica into the amorphous form during the partial vitrification the mass undergoes in firing.

O. Balthasar describes the *manufacture of porcelain flowers* (Monit. céram., 23, 136). The body consists of 20 parts by weight of quartz sand, 15 parts of feldspar, 15 of kaolin, and 2 of calc spar, the plasticity being increased by syrup or gum arabic. The glaze is made from 12 parts of sand, 10 of feldspar, 6 of calc spar, 3 of porcelain sherds, and 3 of calcined kaolin, mixed, and the ware is fired at 1,300°C.

The author (Thonind. Zeit., 19, 453) described the coloration of various porcelain and stoneware glazes by copper oxide. Pure silicates of potassium, sodium, or potassium-sodium ( $\text{RO} : 3\text{SiO}_2$ ) dissolve the oxide and become dark blue in colour. On replacing part of the silica by its equivalent of boric acid the colour assumes a greenish shade, more noticeable with soda glass than with potash glass, and this tendency is intensified in presence of alumina, and by the substitution of the alkaline earths, wholly or in part, for the alkali metals. The lead-alkali silicates fused with silica only, are blue when the molecular proportion of potash is equal to or greater than the lead present; otherwise green, the effect of boric acid and alumina being as already stated. The potassium-zinc and potassium-bismuth glasses are coloured green when the metals are in equal molecular proportions. To raise the fusing-point of these glazes to the necessary degree for use on porcelain, they must be mixed with refractory bases exerting a minimum influence on the colour. The most suitable mixtures for Seger porcelain are:  $1\text{K}_2\text{O}, 0.5\text{ZnO}, 18\text{SiO}_2$ , and  $1\text{K}_2\text{O}, 1.25\text{ZnO}, 5.1\text{B}_2\text{O}_3$ , prepared by the aid of the following frits:  $2\text{K}_2\text{O}, 1\text{ZnO}, 6\text{SiO}_2$ , and  $1\text{K}_2\text{O}, 2\text{ZnO}, 6\text{SiO}_2$ , and mixed with 4 per cent. of  $\text{CuO}$  to produce a fine Turkish blue.

A *New Continuous Furnace* for firing muffle colours and gold decorations is the Fürbringer muffle (Sprechsall, 29, 755). A channel furnace runs round three sides of a square, the fire being in the centre, and, the hot gases being diverted on either side, the ware is progressively heated as it is moved forward until it reaches the maximum, at the point nearest the fire, and thereafter is gradually cooled down in its progress towards the outlet. The pieces are placed in baskets of hoop iron, which can be pushed forward, by suitable means, at each angle of the furnace, at intervals of 6 or 7 minutes, the whole charge of 20 baskets passing through in about 2 hours. This continuous method obviates the loss of heat occasioned by the transference of the ware, in ordinary furnaces, and gives a finer lustre to the colours fired in it.—C. S.

*Stone [Artificial] from Glass Sherds.* Central-Blatt f. Glas-Ind. 11, 293.

See under IX., below.

## PATENTS.

*Metallic Decorations on Earthenware, Glass, and the like, an Improved Printing Process for Producing.* H. Kunze, Kolmar, Germany. Eng. Pat. 19,123, Aug. 29, 1896.

"The printing and fluxing mediums are impressed together;" "the metallic powder, free from flux, is then dusted upon the drawing."—V. C.

*Enamelled Metallic Ware, Impts. in the Manufacture of.* A. Niedringhaus, St. Louis, U.S. Eng. Pat. 21,512, Sept. 29, 1896.

THE process is one "of preparing steel for enamelling, which consists in placing it, a chloride, and saltpetre in the annealing pot, and subjecting the same to the ordinary annealing heat." After this the enamel is applied to the base, and fused thereon.—V. C.

## IX.—BUILDING MATERIALS. CLAYS, MORTARS, AND CEMENTS.

*Stone [Artificial] from Broken Glass.* Central-Blatt f. Glas-Ind. 11, 293.

A NEW building material, called "ceramic stone" by its inventor, Garchey, is being tested in France. The chief raw material is broken glass, which is ground to powder, and de-vitrified by passing it through two furnaces, the second one at a very high temperature. Finally, the now pasty mass is pressed, and thereby acquires form and solidity.—C. S.

*Cements, Hardening of.* E. Caodlot. Baumaterialienkunde, 1896, Heft 1-3.

THE abnormal phenomena sometimes observed in using cements are, in almost all cases, referable to very simple causes. Of these, the following are some of those more frequently occurring:—(1.) The behaviour (solubility and crystallisation) of the aluminates, which plays such an important part in the hardening of cements, is varied (a) by the presence of other substances, and (b) by the hydration of the aluminates by exposure to the air or contact with moist sand. (2.) The carbonation of the free lime in the stored cement by the carbonic anhydride of the air. (3.) The presence of calcium sulphate, which often causes the crumbling of cement introduced into water immediately after mixing.—L. T. T.

*Portland Cement, Impt. of, by Admixtures.* L. Erdmenger. Thonind. Zeit. 20, [51], 757, [53], 786—788.

THE result of Landteigen's experiments with admixtures of Portland cement and a siliceous American earth resembling trass (Thonind. Zeit. 20, [32]) agree with those obtained in a northern laboratory, where an admixture of a siliceous by-product was employed in conjunction with sand, the advantage being attributed to combination of the siliceous material with the free lime in the cement, whereby the tendency of the latter to crumble is counteracted. The results, as regards the cohesive power of the mixed cement

at the end of a year, appear, from the tables given, to have been generally more favourable in proportion to the increase of siliceous material, up to between 20 and 50 per cent. (ratio of cement to sand, 1:3), according to the cement used. In two series of tests with a lightly burnt cement, it was found that the addition of from 10 to 25 per cent. of siliceous material rendered the product more durable than the unmixed fully burnt cement, especially when the semi-calcined article was previously slaked. This siliceous material differs from the American earth and trass in being more effective when previously dried, whereas the converse is the case with the two latter.

The author considers that greater value ought to be attributed to the increased durability imparted to the cement by the admixture of siliceous matter than is at present the case, more stress being now laid on quick-setting than on permanence.—C. S.

*Clay for Brickmaking, Increase of Content in Sulphates during Firing.* H. Günther. *Thonind. Zeit.* 1896, 20, 583.

BRICKS of a certain brand, when employed in building construction, regularly developed a whitish efflorescence consisting almost entirely of potassium and sodium sulphates; although the same bricks when stacked alone (without mortar intervening) remained practically unchanged for long periods of time, and although the clay from which they were made contained little more than traces of sulphates. It is generally assumed that an increase in soluble salts (especially sulphates) occurs during the firing of bricks, under the influence of certain constituents of the flue-gases. The author shows that such an increase likewise occurs even when fuel free from sulphur is employed, if the clay contain pyrites—as was the case in the present instance. As regards the source of the efflorescence, this was found to arise from the interaction of gypsum contained in the bricks with alkalis derived from the intervening mortar.—H. T. P.

*Wood, Treatment of, with Antiseptics prepared from Petroleum.* A. W. Adiasiewitsch. *Trudy. bak. otd. imp. russk. Tech. obschtsch.* 1896, 11, 243.

THE resinous matters obtained from petroleum by the author's previously published method (this *Journal*, 1896, 346 and also 267) are superheated by agitation with heated plates, and then distilled at 350°–400° C. The product flows in cascade fashion in a thin stream, through an air-tight cast-iron chamber, heated to 450°–480° C. The vapours produced are led into a still, filled with the same product at its boiling point. These vapours, owing to their higher temperature, much assist the distillation. A condenser, protected from too rapid cooling, is attached to the still. By this process, 75 per cent. of antiseptic compounds were obtained from a resinous substance prepared from a petroleum-still residue. Nine per cent. remained as a tar in the still.

Machinery-oil residues, yielded resinous matter producing 58 per cent. of antiseptic compounds and 24 per cent. of tarry matter. The average composition of the antiseptic liquid, was 20.9 per cent. of oils, boiling below 300° C.; 31.2 per cent. between 300°–400°; 6.7 per cent. of solid anthracene; 4.2 per cent. of phenols; 8.0 per cent. of naphthalene and 10 per cent. of coke. Treatment with hydrochloric acid extracted basic oils containing aniline. The author considers that these together with the anthracene oils, form the real antiseptic agents; whilst the resinous constituents of the mixture confer on the wood greater density and durability. The wood must be carefully dried before treatment. The usual steaming is a mistake, since the after vacuum treatment fails to remove all the moisture. Treatment with the vapours from the boiling antiseptic is better. These coagulate the albumins, but at the same time expel all moisture. The usual vacuum treatment follows, and then treatment with the antiseptic fluid under 3½–4 atmos. pressure.

The light hydrocarbons retained in the pores of the wood seem to dissolve the antiseptic, and to assist its permeation. Dried wood absorbs more of the antiseptic than steamed wood; but wood treated as described above,

absorbs still more. Wood so treated loses 2–6 per cent. in weight in the first three months, owing to evaporation of the lighter antiseptic oils. A further loss is not advantageous, and may be prevented by dipping the wood at this stage for 2–3 minutes in the tar, heated to 150–200° C., which remains as a still-residue when preparing the antiseptic. This tar penetrates about 1 mm. in depth, and forms an impermeable outer coating.—J. B. C. K.

## PATENTS.

*Artificial Stones, Manufacture of [Use of Electricity].* E. Conlon and J. J. Defalque, Blaton, Belgium. Eng. Pat. 23,018, Dec. 2, 1895.

The inventors claim the use of electricity as a petrifying agent, in the manufacture of artificial stone.—V. C.

*Kilns for Use in the Manufacture of Bricks, Terra-Cotta Goods, Tiles, and the like; Impts. in.* J. W. Ormrod, Bolton. Eng. Pat. 1794, Jan. 25, 1896.

A SERIES of chambers is placed on each side of a central flue, which serves for both. From the chambers, passages leading to the central flue conduct steam to a chimney. A partition in the central flue provides a passage for the smoke, which escapes by a second chimney. Any one of the chambers can be used as a separate kiln.—V. C.

*Kilns or Furnaces, Impts. in, Applicable for Burning Lime, Cement, and other Minerals.* H. Simmonds, Colne, Lancs, and John Delaney, Horton-in-Ribblesdale. Eng. Pat. 2843, Feb. 7, 1896.

The gases and products of combustion from the gas producer are raised to "a white heat" in a combustion chamber, supplied with heated air, before being admitted to the kiln.—V. C.

*Wood, An Improved Composition for use in Imitation of or in Substitution for.* F. L. Schauer mann, Twickenham, and J. S. Cowper, London. Eng. Pat. 6232, March 20, 1896.

This composition is produced "by the action of nitric acid on a mixture consisting essentially of comminuted or disintegrated wood and a siccativ."

The following proportions have been found suitable, viz., sawdust, 1 pint; sulphate of zinc or sulphate of copper or a mixture of both in any proportions, ¼ pint; powdered rosin, 2 oz.; nitric acid, ¼ pint; and linseed oil, 2 fluid oz.—V. C.

## X.—METALLURGY.

*Gold, Chemistry of the Cyanide Process for Extracting.* G. Bodländer. *Zeits. für angew. Chem.* 1896, 583–587.

THE reaction which occurs in the solution of gold by potassium cyanide, was supposed by McArthur to take place according the equation—

It has been shown, however, by MacLaurin, Goyder, and others that atmospheric oxygen takes part in the action, thus:—

The author finds that the reaction is not so simple as this equation would indicate, but that it takes place in two stages. In the first of these, hydrogen dioxide is formed—

and the reaction then proceeds without further aid from the atmospheric oxygen—

Using pure gold, 90 per cent. of the amount which is theoretically soluble in this manner, may be dissolved by a given quantity of potassium cyanide.

The rate of solution of gold in alkali cyanide solutions increases with the concentration of the latter, thus the times required for the solution of 46 sq. cm. of gold leaf

(= 7.1 mgrms.) in 20 c.c. of 0.1, 0.25, 1 and 3 per cent. solutions of potassium cyanide, are approximately 12, 5, 4, and 3 mins. respectively. This does not accord with the statement of MacLaurin that a maximum rate of solution is obtained with a 0.25 per cent. solution.

The solution of gold by reagents so indifferent as potassium cyanide and (at ordinary temperatures) oxygen, is best accounted for by the theory of free ions. In its simple salts, gold is present as cation, but it cannot be made to replace hydrogen, and cannot be brought into the ionic state by the energy produced by the oxidation of hydrogen. Solution, in fact, occurs owing to the gold entering into union with cyanogen and forming a complex anion—

In view of the fact that hydrogen dioxide acts upon hydrocyanic acid, with the formation of oxamide, as Radzi-zewski has shown (Ber. 18, 355), the production of hydrogen dioxide in the above reaction may to some extent explain the loss of hydrocyanic acid which is experienced in practice.—E. B.

*Gold, Detection of, in Sea Water: also Oxidation of Ferrous Sulphate by Sea Water.* E. Sonstadt. Proc. Chem. Soc. 12, 236.

REFERENCE is made to the author's papers (Chem. News, 25, 196, 231, and 241) relating to the presence of calcium iodate in sea water, and to the absence in existing analyses of sea water of the recognition hitherto of the presence of any salt capable of acting as an oxidiser. Results were obtained which point to the presence in sea water of other oxidising salts besides calcium iodate, which is not in sufficient proportion to account for all the facts ascertained.

In the second part of the paper, on the detection of gold in sea water by means of mercury, experiments are described, in which pure mercury was agitated with sea water and then volatilised in a porcelain crucible. The black film left behind was digested in strong hydrochloric acid, which removed silver and other metals, leaving a stain, soluble in *aqua regia*, giving a minute gold bead on cupellation. It is suggested that the precious metals are probably present in sea water in a free state, owing to molecular strain from the great dilution of their salts.

The preceding experiments were made in 1895, on the Great Eastern Railway Company's sea water, conveyed in oak kegs. Reference is made to unpublished experiments on sea water from the same source, made a few years ago, in which assays were made of the ferric oxide obtained by treating the sea water, slightly acidulated, with ferrous sulphate, which experiments showed that water from this source was much poorer in gold than the water of the Irish Sea, on which the author's first experiments in 1872 (Chem. News, 26, 159) were made.—E. S.

*Gold, Absence in Granite Rock of Bald Mountain District, Wyoming.* F. D. Smith. Eng. and Mining J. 62, [23], 1896, 535.

THE author was sent down to confirm or refute the report that the whole of the granitic rock in this district contained gold. The manager of the Fortunatus Company, which works the conglomerate of this locality for gold, had asserted the presence of gold as a "telluride." The author's results show that no gold is present, and that the report was erroneous.—J. B. C. K.

*Silver and Uranium Mines at Joachimsthal, Bohemia.* R. Hilmacher. Eng. and Mining J. 62, [23], 1896, 533—534.

THE mine was originally worked for silver, which exists in rich pockets, but, owing to the wide space over which such pockets are scattered, greater attention was at length paid to the cobalt, nickel, bismuth, and uranium, formerly considered as by-products. Owing to the high value of the uranium, more recent development has been chiefly undertaken in this direction, and the mine is now an

uranium mine, with silver and the other metals considered as by-products. Besides developing the mine, the old waste heaps from the early workings have been utilised with satisfactory results. The ore is usually massive or in grains, with a colour from greyish to velvet-black, and a dull, submetallic, pitch-like lustre. If pure, the composition should be  $\text{U}_3\text{O}_8$ , but analysis shows that it contains only 68.5 to 86.5 per cent. of  $\text{U}_3\text{O}_8$ , whilst the admixtures are  $\text{FeO}$ , 2 to 5.7 per cent.;  $\text{CaO}$ , 0 to 5.8;  $\text{MgO}$ , 0 to 0.5;  $\text{SiO}_2$ , 2.4 to 5.4;  $\text{PbS}$ , 2.8 to 0.6;  $\text{PbO}$ , 0 to 0.7;  $\text{Al}_2\text{O}_3$ , 0 to 0.3;  $\text{Bi}_2\text{O}_3$ , 0 to 1.2;  $\text{Bi}$ , 0.5 to 0.6;  $\text{Cu}$ , 0 to 3.9;  $\text{CO}_2$ , 0 to 3.3;  $\text{MnO}$ , 0.1 to 0.8;  $\text{As}$ , 1.2 to 4.3;  $\text{Zn}$ , 0 to 0.7; and  $\text{H}_2\text{O}$ , 0.4 to 2.6; together with  $\text{SO}_3$ ,  $\text{V}_2\text{O}_5$ , and traces of other metals. The coloured ores are all derived from this black species. It is stated that in no other district in the world is uranium ore found in extractable quantity, and the works erected at Joachimsthal for its conversion into colours for use is the only one in existence, and the Crown monopolises the trade.

The treatment of the dressed ore is as follows:—It is first calcined in a reverberatory furnace to decompose the sulphides, arsenides, &c., after which 15 per cent. of sodium carbonate and 2 per cent. of sodium nitrate are added, and the whole again strongly heated. The  $\text{U}_3\text{O}_8$  is thereby converted into a form readily soluble in dilute acids, whilst the impurities are transformed into salts soluble in water. The latter are extracted with hot water, and the uranium oxide dissolved in dilute sulphuric acid. Caustic soda is added in excess to the sulphate solution, so as to precipitate other metallic oxides whilst re-dissolving the uranium hydrate. This solution, after separation, is treated with sodium carbonate, and yields an insoluble sodium uranite,  $\text{Na}_2\text{U}_2\text{O}_7 + 6\text{H}_2\text{O}$ . This is the original process of treatment, and, with the addition of a few improvements, is that now in use. The dressed ore treated in 1887 was 30 cwt., at 337 florins per cwt., whereas in 1894 it was 87½ cwt., at 657 florins per cwt. The marketable products consist of a yellow-orange or dark orange uranite of soda, a hydrated compound of the formula  $\text{U}_2(\text{NH}_4)_2\text{O}_7 + 6\text{H}_2\text{O}$ , and the black oxide, and they are used for glass staining and porcelain painting. The output is variable, amounting to from 20 to 120 cwt. per annum. Two-thirds of the production of 1895 was consumed in Austria, whilst one-third only was exported.—A. W.

*Steel, Use of Phenol (Carbolic Acid) for Tempering.*

M. Levat. Comptes. rend. 123, 945.

THE author describes experiments made with chisels and with ingots.

In the former case, the chisel, tempered to a blue tint in carbolic acid, was superior in hardness to the one tempered at a cherry-red in water. The ingots, of ordinary cast steel and of rolled steel, showed a similar improvement in hardness, elasticity, and also in grain when tempered at a white heat in carbolic acid. The amount of carbon in the steel was not increased by tempering in carbolic acid.

—J. B. C. K.

*Aluminium, Behaviour towards Ammonium Compounds; and the Utilisation thereof for the Chemical Modification of the Surface of the Commercial Metal.* C. Goettig. Ber. 29, 1671.

THE fact that, by the action of alkaline bases, of hydrofluoric acid, and other substances upon aluminium, an alteration of the surface colour of that metal can be produced, caused by the elimination of certain impurities through the above-named agents, suggested the attempt to produce a similar result by a treatment resulting in the partial solution of the aluminium, but without interfering with the impurities contained in it. Such a treatment, which is generally accompanied by a brownish discoloration of the metal, consists in the action upon aluminium of very dilute solutions of ammonia, or of ammonia and ammonium salts. In the first case dark brown tints are obtained, in the second case light brown ones. The reaction taking place appears to be expressed by the equation—

the soluble aluminium aluminate subsequently splitting up into insoluble alumina and ammonia.—C. O. W.

#### PATENTS.

*Cast Steel and Homogeneous Iron [Furnace Lining].*  
Impts. in the Manufacture of. J. Gjers, Middlesbrough-on-Tees. Eng. Pat. 22,727, Nov. 27, 1895.

AN ordinary open-hearth steel-melting furnace is lined on its bottom and sides with a rich natural or artificial iron oxide on a silicious or magnesia foundation. If a granulated iron ore be used, it is damped with brine to ensure a caked and solid bottom. The furnace may be charged with crude pig-iron, either cold or run in fluid, and the temperature is high enough to maintain the charge in the liquid state after its conversion into steel, which, after tempering with ferro-manganese or ferro-silicon, is run off into ingots. It is stated that crude pig-iron containing much or little phosphorus may, with equal advantage, be boiled, as described, on a rich iron cinder bottom. Reference is made to the inventor's patents of 1867, 3440; 1894, 2720; 1895, 10,815 (this Journal, 1896, 457); and 1896, 123 (abstract following).—E. S.

*Cast Steel and Homogeneous Iron [Duplex Furnace].*  
Impts. in Furnaces for the Manufacture of. J. Gjers, Middlesbrough-on-Tees. Eng. Pat. 123, Jan. 2, 1896.

A DUPLEX furnace is described, consisting of two open-hearth furnaces, arranged at a small angle side by side, connected at the rear ends by a semi-circular flue, and having a combustion chamber in front of each furnace, each chamber being surmounted by a regenerator, preferably of the cellular type, with reversing mechanism. The bottoms and linings of the furnaces may be of iron oxide, as described in the previous abstract of Eng. Pat. 22,727, 1895, or they may be of acid or basic material. A fan is used to supply a mild air blast. In working, the hot gases from one combustion chamber pass into the corresponding furnace, melting the material upon the bed, and then traverse the connecting flue and melt crude pig-iron on the bed of the second furnace, whilst the charge in the first furnace is being converted into finished steel. The fire gases then pass through the second combustion chamber, in which the fuel has been allowed to burn low, and through the regenerator above, which they heat, whence they have exit to a chimney. The reversing takes place when the crude pig-iron has been brought to the melting stage in one furnace, and the finished steel been tapped from the other furnace. A modified duplex furnace is also shown, in which each combustion chamber is provided at its forward end with a number of passages through which producer or other combustible gas can be admitted from an underground gas flue, thus dispensing with solid fuel without disturbing the general arrangements.—E. S.

*Iron and Steel and other Metals, Process for the Direct Production of, from their Ores.* E. J. M. Servais, Luxemburg, and P. Gredt, Esch-on-the-Alzette, Luxemburg. Eng. Pat. 2997, Feb. 10, 1896.

THIS is a "process for the direct production of iron and steel and other metals from their ores by smelting the latter under admixture of easily fusible reducing bodies, fats, oils, resins (for example, petroleum and petroleum residues) under partial or complete exclusion of the air, or by the introduction of the mixture of the ores with the reducing substances into the liquid-bath in the melting furnace, or by melting the spongy iron produced from iron ore by the reduction by means of oils or reducing gases, such spongy iron being protected against oxidation by a coating of a protective compound of iron with nitrogen or other suitable element, or by the introduction of the spongy iron produced, into the liquid-bath of the smelting furnace, whether continuously by means of a feeding worm or intermittently by a piston."—E. S.

*Amalgam, An Improved [Copper-cadmium Amalgam] for the filling of Hollow Teeth.* W. Randler, Friedland, Mecklenburg. Eng. Pat. 23,050, Dec. 2, 1895.

PRECIPITATED copper is mixed with mercury and 1 to 14 per cent. of cadmium is added so as to hasten its hardening.—J. H. C.

*Metallurgical Furnaces [Annealing tubes], Impts. in.*  
G. Platt, Wednesbury, Stafford. Eng. Pat. 23,355, Dec. 6, 1895.

THE furnace is a combination of a fire-place, an annealing chamber, and of drying stoves, one on either side of a central flue, which the fire-gases enter, after their passage through a pair of lower flues and the annealing chamber. The apparatus is applicable to annealing and drying seamless steel and other metal tubes, rods, bars, sheets, &c. The annealing chamber is placed immediately above the two lower flues, and is surmounted by drying stoves and the upper central flue. When the annealing chamber is required for close annealing, it is heated by side flues as well as by those beneath, the gases in this case passing on to the upper flues without traversing the annealing chamber.—E. S.

*Nickel Ores, and other Materials containing Nickel, Impts. in Apparatus for treating with Carbon Monoxide.* L. Mond, London. Eng. Pat. 23,665, Dec. 10, 1895.

THE apparatus consists mainly of two upright cylinders containing superposed trays, down the series of which nickel ore is caused to descend to the bottom. The first cylinder, into which the ore is first charged, receives, near the bottom, a current of a reducing gas, such as water-gas, or producer gas containing hydrogen, which traverses the column. A compartment beneath each of the upper trays is connected by a side flue to a stack-shaped combustion chamber, from which heating gases enter, and by another flue to a chimney, so that the heating gases do not mingle with the reducing gases led up the cylinder. The lower compartments are provided with taps connecting with a water or air supply for cooling the descending ore. The second cylinder, or "volatiliser," receives the ore, now containing metallic nickel, from the reducing cylinder, and this is caused to descend from tray to tray, whilst a stream of carbon monoxide is led into the lower part of the volatiliser, and is taken from the upper part into cooling chambers, in which nickel is deposited from the gaseous compound formed. A pair of conveying columns is set between the two cylinders, receiving respectively, by suitable mechanism, the ore discharged from the bottoms, and delivering the same to the top of the opposite cylinder, so that the ore is subjected successively to repeated alternate treatment in the two cylinders. A special rotary feed valve is described and shown, to enable this interchange to be effected without permitting mixture of the different gases employed. (Eng. Pat. 23,665 A, Dec. 16, 1895. See page 34.)—E. S.

*The Treatment of Metals [Alloying with Chromium].*  
Impts. relating to, and to Products resulting therefrom.  
E. Placet, Paris. Eng. Pat. 202, Jan. 3, 1896.

PURE chromium, coated with another metal (such as copper, nickel, aluminium, gold, silver, &c.), is introduced into the fused metal or alloy with which it is desired to alloy it. The purpose of this coating is to prevent—at the moment of its introduction into the molten metal or alloy—the oxidation of the chromium. One or other of several specified metals may be simultaneously introduced. The solution of the chromium in the fused metal is facilitated, it is said, by the addition of auxiliary metals, and also of certain oxides and salts. The improved properties of the chromium alloys thus formed in respect to various applications, are described.—E. S.

*Caustic Soda, Carbonate of Soda, and Sulphide of Sodium, Impts. in the Manufacture of.* H. R. Angel, London. Eng. Pat. 335, Jan. 6, 1896.

See under VII., page 43.

*Gold, Silver, or Platinum, Treatment of Antimonial and Arsenical Ores, Materials, or Furnace Products, containing.* W. Blackmore, Sheffield. Eng. Pat. 519, Jan. 8, 1896.

THE material is fused with an alkali or alkaline compound, such as carbonate of soda, together with sulphur or some suitable sulphur compound. A reverberatory furnace may be employed at a dull red heat. The fused mass is treated with water when the arsenic and antimony go into solution, and the precious metals remain in the residues and may be recovered by smelting.—J. H. C.

*Gold and other Metals, Impts. relating to the Extraction of, from Ores, Tailings, Slimes, and other Compounds containing the same, to Apparatus therefor, and to the Preparation of Solvents for Use in such Extraction.* H. R. Lewis, London, and C. Gelstharp, Manchester. Eng. Pat. 23,052, Dec. 2, 1896.

THE material in a fine state of division is treated with a solution containing hypochlorous or hypobromous acid or other oxy-acid of chlorine or bromine, with or without admixture of other suitable chloride or bromide; or it is mixed with bleaching powder or bleaching liquor, and carbonic, acetic or other suitable acid is added; or it is mixed with a finely divided carbonate, sulphate, phosphate, arseniate, or oxide and water, and then gaseous or liquid chlorine or bromine, or hypochlorous or hypobromous acid is added. The mixture is agitated when necessary until all the gold is dissolved. The gold is precipitated from the solution by carbon, sulphuretted hydrogen or other suitable precipitant; or by means of a current of electricity, in which case the chlorine, hypochlorous, or hypobromous acid, liberated at the anode, may be conveyed into tanks containing milk of lime, so as to be employed again. If the material contain silver, salt or other suitable chloride may be employed so as to dissolve the whole of it with the gold, or if little or no chlorides are present the hypochlorous acid will convert it into silver chloride, which will remain with the solid residue, from which it may be removed, after separating the gold solution, by means of a strong solution of salt or by hyposulphite of soda [thiosulphate] solution, and precipitated by electrolysis or other means.—J. H. C.

*Previous Metals, Impts. in or relating to the Extraction of, from their Ores.* W. H. James, and C. J. Norris, London. Eng. Pat. 23,492, Dec. 7, 1896.

THE substance obtained by saturation of bromine with the oxides of nitrogen (called "nitrobromine"); or the somewhat similar substances formed "when any halogen is acted on by the oxides of nitrogen"; or a "substance formed by heating to dull redness equal weights of bleaching powder and potassium cyanide," or "potassium hypochlorite or hypobromite, with or without the addition of hypochlorous or hypobromous acid" is used alone or added to the cyanide solution ordinarily employed in treating gold ores so as to increase its solvent action.—J. H. C.

*Extracting Metals [Amalgamation], Impts. in Apparatus for.* E. Fischer, Breslau, and C. G. Penney, London. Eng. Pat. 19,883, Sept. 9, 1896.

THE mercury is heated in a retort, heated air being forced in at the same time. The mixture so produced is conducted by a pipe covered with a heat insulator, and returned axially into a slightly inclined drum and cylinder which are made to rotate. Within the cylinder the pipe is perforated. The wet or dry material to be treated is introduced at the upper end of the cylinder and gradually makes its way into the drum where it comes in contact with the heated air and mercury vapour, and forms an amalgam which is deposited on the inner surface of the drum. The drum is constructed of copper, its inner surface is amalgamated and made to form the cathode of an electric circuit while an anode of carbon or other suitable material is suspended from the axial pipe.—J. H. C.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### (A).—ELECTRO-CHEMISTRY.

#### PATENTS.

*Electric Battery [Primary], An Improved.* P. Falle, Toulouse, France. Eng. Pat. 22,142, Nov. 20, 1895.

THE claim is for "An electric battery in which the negative pole is formed of a sheet of zinc immersed in a solution of chloride of sodium or chloride of zinc, the positive pole being formed of a cylinder of porous carbon containing an agglomerate composed of sulphate of zinc, a double sulphate of aluminium and potassium and of potassium bichromate, these substances being ground and mixed to a thick paste with sulphuric acid."

The agglomerate is made up of equal weights (100 grms.) of alum, potassium bichromate, sulphate of zinc, and sulphuric acid.—J. C. R.

*Ozone, Impts. in or relating to the Manufacture of and Apparatus therefor [Corrugated Glass Plates].* C. J. Yarnold, Brixton, London. Eng. Pat. 24,289, Dec. 18, 1895.

IN this apparatus the gas or air treated, is first purified by means of caustic soda, and then dried and cooled to a temperature of 32° F. It is then passed into an expansion chamber provided with a thermometer, and thence into the ozoniser proper, which consists of a number of compound plates, each formed of a sheet of corrugated glass, enclosing between them a layer of silver foil, which forms a "tab" or extension, connected by means of a screw and washer to its respective terminal. There are two terminals, one on either side of the box. The plates are cemented at their edges, and arranged so that the summits of the waves on one plate are opposite the depressions of the next. Each compound plate is let into the casing of the apparatus, which is formed of insulating material, preferably slate. Their lower edges are placed between ribs on the floor of the casing and their upper edges are insulated from each other by fingers extending from a bar secured to each sleeve. Any oxides which may be formed are dealt with as in Eng. Pat. 12,692, 1895.—G. H. R.

*Electrodes [Carbon], Impts. in and relating to, for Use in the Production of the Electric Arc.* J. A. Deuther, Boston, U.S.A. Eng. Pat. 20,600, Sept. 17, 1896.

THE object is to construct one or both of the opposite electrodes at the point where the arc is formed with a section of carbon in any form (but where found useful, composed of alkaline earths and carbon), which, when consumed, can be replaced by a similar section, without disturbing the other parts of the electrode.—J. C. R.

*Electric Furnaces [Calcium Carbide and reduction of Refractory Compounds], Impts. in and relating to.* J. A. Deuther, Boston, U.S.A. Eng. Pat. 20,601, Sept. 17, 1896.

THE inventor shows an oscillating electrode and mechanism whereby material to be smelted is fed within the path of the arc.—J. C. R.

### (B).—ELECTRO-METALLURGY.

*Electro-Chemistry, Inorganic, recent Progress in.* C. Chéneveau. Rev. d. Phys. et d. Chimie. 1, 55—62.

THESE notes are mostly derived from papers read before section X. at the Congress of Applied Chemistry in Paris, July 1896.

*Treatment of Tin Scrap.*—The electrolytic recovery of tin from this material, is now carried out with a 10 per cent. sodium hydrate solution containing sodium chloride as an electrolyte. 10 per cent. of the tin remains dissolved in the electrolyte as a stannate. Both the tin and the alkali may be removed from this by chemical methods.

*Miner's Aluminium Process.*—Data are given of experiments carried out at St. Michel, Savoy. A mixture of 70

per cent. of sodium chloride, and 30 per cent. of a natural or chemically prepared cryolite is used in the bath. Bauxite and aluminium fluoride are fed into it, as the electrolytic process continues. 80 kilos. of this mixture are used as a charge; its melting point is  $675^{\circ}\text{C}$ ., 10 h.p. hours are required to produce 1 kilo. of aluminium. The current efficiency is 70 per cent. The voltage is 7.5, of which only 3 volts are actually used in separating the aluminium. A secondary reaction due to the free hydrofluoric acid and the deposited aluminium, has been said to absorb 25 per cent. of the current. Experiments with Heroult's process at Froges do not confirm this. The difference of potential observed at the terminals of the bath, varies with the nature of the electrodes. With electrodes of copper, platinum, and carbon it is *nil*; whilst between carbon and molten aluminium it is at a maximum. It also varies proportionately with the current intensity.  $E = 3.1 i$  for a current density below 10 amperes per sq. ft. Above this limit it can be calculated from  $E = e + ri$ , where  $e$  = voltage required to decompose the aluminium salt, and  $r$  = the resistance of the electrolyte;  $e = 3$  volts at  $800^{\circ}\text{C}$ ., and  $= 2$  volts at  $1100^{\circ}\text{C}$ .;  $r$  is about 0.00125 ohm;  $e$  and  $r$  have been experimentally proved constant for currents between 1,000—4,000 amperes. Minet estimates that 20,000 h.p. is used for aluminium production in France, and that the use of natural power would allow it to be obtained for  $\frac{1}{10}$ th of the present cost.

**Güntz's Lithium Process.**—If a mixture of equal parts of potassium and lithium chlorides be electrolysed with a current of 10 amperes at 20 volts and a temperature of  $450^{\circ}\text{C}$ ., lithium will be produced. The temperature must be kept above the melting point of lithium chloride, otherwise a subchloride of lithium will be formed from the deposited metal.

**Electrolysis of Sodium and Potassium Chloride Solutions.**—Minet states that asbestos diaphragms give the best results. As anodes, Peyrussou's silver coated with platinum or iridium, Hoepfner's ferro-silicon and graphitoid carbon obtained by the methods of Castner and others, are mentioned.

**Electrolysis of Fused Salt.**—Hulin describes renewed experiments with the Vautin process, carried out at Modane, Savoy. Molten lead forms the cathode in this process. The unsatisfactory results obtained in earlier experiments were due to the formation of subchlorides, and to the liberation of the sodium in globules, which did not alloy rapidly with the molten lead. These difficulties are overcome by electrolysis of a definite mixture of sodium and lead chlorides, the bath being continually fed with the same. The anodes are formed of receivers containing lead, and receive only part of the current. A portion of the liberated chlorine acts on the lead, and the lead chloride formed diffuses into the bath. By regulating the current passing through the molten lead anode, the amount of lead chloride formed can be increased or diminished. The best current density is 0.7 ampere per sq. ft., and produces 0.081 kilo. of Cl, and 0.054 kilo. of sodium per h.p. hour.

An E.M.F. of 7 volts is required. Peroxide of lead, and alloys of sodium or barium with tin or zinc, may also be obtained by this method.

**Plating on Aluminium.**—Margot's process consists in removing the thin film of oxide which causes non-adherence of the deposit, by immersion in a solution of alkaline carbonate, followed by treatment with hot hydrochloric acid (1 in 20) and final immersion in a dilute copper sulphate bath. The ordinary electrolytic process is then proceeded with. The same preliminary operations are necessary, in silvering aluminium by Wagner's process. If the solution used be that of the double cyanide of silver and potassium, the best results are obtained by coating the aluminium first with zinc. Copper cannot be used.

—J. B. C. K.

**Copper, Silver, and other Metals, Hoepfner's Electrolytic Process for the Production of, directly from the Ores.** Eng. and Mining J. 1896, 62, [23], 584.

THE powdered ores are first leached with a warm solution of cupric chloride, containing some chloride of sodium or

calcium, by which the silver, copper, lead, bismuth, and some iron and arsenic are extracted. From the solution containing cuprous chloride, the silver is precipitated by metallic copper, the chloride of lead deposited by cooling, and the antimony, bismuth, and arsenic precipitated by powdered limestone. Finally, the iron, when in excess in the solutions, is separated by the action of  $\text{H}_2\text{O}_2$  according to the following equation:—

The solution of cuprous chloride thus purified is then conveyed to the electrolytic baths, which contain cells with anodes of artificial carbon and cells with cathodes of sheet copper, separated from each other by diaphragms consisting of linen, cotton, or the like. This solution is divided into two separate currents, of which one brought into contact with the cathodes, loses all or part of its copper contents, whilst the other, brought in contact with the anodes, is reconverted into a solution of cupric chloride. After leaving the bath the currents are reunited, thus forming a solution of cupric chloride similar to the original one for the treatment of the ore. If zinc or nickel be present in the ore, all or part of it will be extracted and can be electrolytically deposited from the purified solution.

In a series of baths first the copper, then the lead, nickel, and zinc will be deposited. The cost of extracting the various metals is given, and owing to the better electrical conductivity of the chloride solutions as compared with the sulphate hitherto used, twice the amount of copper can be deposited in the same time with the same current. Analysis of the copper thus directly obtained from ores containing considerable impurities, show that it is practically pure.

By means of the process described, neither gold nor the whole of the zinc is extracted. If these metals be present in remunerative quantity the ores or the residue of the ores subjected to the preliminary extraction of copper and lead, are roasted in an ordinary furnace to convert the sulphides into oxides, and the gold is then extracted by chlorides. The oxide of zinc is converted into chloride by means of chloride of calcium or any other convenient means, and the metal electrolytically deposited with the simultaneous production of free chlorine.—A. W.

**Slimes (Copper). Present Method of Treating, from the Copper Refineries.** T. Ulke. Eng. and Mining J. 1896, 62, (22), 512.

IN the electrolytic method of refining copper, the slimes, after screening from scrap copper, constitute about 4 per cent. of the total weight of the anode copper refined, and contain on an average from 15 to 30 per cent. of copper, 15 to 50 per cent. of silver, less than 1 per cent. of gold, and from 20 to 35 per cent. of arsenic, antimony, tellurium, and other impurities. The usual dry methods of treatment with various charges in lead refining all have the objection that part of the silver and copper can be recovered only by treating quantities of by-products such as litharge, copper matte, or speiss. The wet method as carried out by the Baltimore Electric Refining Company, consists of treating the screened slimes in lead-lined vats with dilute sulphuric acid [1 to 4], through which air is injected, for two or three hours. The solution, containing arsenic, copper, and most of the impurities, is siphoned from the residue, which contains lead sulphate, tellurium, a little bismuth and antimony, in conjunction with the silver and trace of gold. This residue is melted on a cupel hearth, at first without any flux, when a brownish slag containing lead and antimony, together with some silver prills, is skimmed off. The slag, after cooling, is picked over to separate the silver and is then added to molten lead in the cupelling furnace, by which means the last traces of gold and silver are removed therefrom. The second stage of treating the slimes, after removing the brown slag, consists of heating with nitre, which extracts the tellurium. The silver metal on the cupel is now practically pure with the exception of a little copper, and is cast into bars ready for parting in the usual way. The copper in the acid solution obtained by the first treatment is recovered by means of scrap iron.—A. W.

*Separation of Metals, Electrolytic, by Use of Soluble Anodes.* R. Pauli. *Elektro-chem. Zeits.* 1896, 3, 180.

The author notes that in the Daniell type of cell, the solution of the one electrode and deposition of a metal on the other, depends upon the relative osmotic pressure of the two metals towards the electrolyte used. If a solution of mixed salts surround the cathode, that metal will be first deposited which for the given electrolyte, exerts the least osmotic pressure. A separation of metals is thus possible without use of dynamos; and as a current will be at the same time produced in the depositing cell, this method may in some cases be cheaper than the usual one.—J. B. C. K.

*Copper Refining, Electrolytic, in the United States.* G. Kroupa. *Oesterr. Zeits. Berg. u. Hüttenw.* 1896, 55, 541.

A COMPARISON of the "multiple" and "series" systems of vat-working. In the former the vertical electrodes are hung on copper bars, which serve as current conductors and run along the length of the vats. In the series system, only the first and last plates in a vat are connected to the current conductors; all the intervening ones being insulated. Although the latter arrangement has been much experimented with in the United States, it is now being given up. Barnett states that in comparing the working of these two systems, one must note (a) Current efficiency; (b) Amount of copper locked up in the vats; (c) Working costs; (d) Capital outlay on plant. The multiple system (M.) requires low E.M.F. and gives 95 per cent. of efficiency; the series system (S.) requires high E.M.F., and, owing to short-circuiting through the vat walls and silver mud, the current efficiency is only 85–90 per cent. The locked-up copper is only half so great with (M.) as with (S.), whilst much more impure anode copper may be safely used. The capital outlay is greater with (M.) than with (S.). Balancing these various items, the total cost with (M.) is found to be about 88.4d. per ton of refined copper less than with (S.). The Anaconda Refinery has changed its entire system from the series to the multiple.—J. B. C. K.

#### PATENTS.

*Multi-farious Ores and Products, An Improved Process for the Treatment of.* [Matte Anodes.] E. A. Ashcroft, Grays, England. Eng. Pat. 14,783, Aug. 3, 1895.

The process, which is an improvement on that described in Eng. Pats. 13,859, 1894, and 13,531, 1895, consists in the employment of anodes composed of iron or copper mattes in a zinc-depositing bath, which has been prepared by leaching roasted zinc ores with a solution of ferrie salts. The solutions of copper and iron thus obtained are electrolysed in vats provided with diaphragms between carbon anodes and copper cathodes, where the copper is deposited, and all the iron raised to the ferrie state, and the solution is thus regenerated ready for leaching a fresh quantity of zinc ore. The copper may be removed from the solution by the simple cementation process of the contact of metallic iron, or soluble iron anodes may be employed in the electro-deposition of the copper, in which case the electro-motive force developed, is utilised for the deposition of the zinc by suitably connecting the baths. If pure zinc be required, a diaphragm must be dispensed with in those cases where the product desired is an alloy of the different metals. The proportion of the metallic salts in solution is then maintained sufficiently constant to ensure a uniform product.

—G. H. R.

*Zinc Impts. connected with the Electrical Deposition of.* R. Heathfield and W. S. Rawson, London. Eng. Pat. 23,097, Dec. 3, 1895.

The zinc iron couple employed for enriching the alkaline bath, as described in Eng. Pat. 16,105 (this Journal, 1895, 874), is, according to this improvement, hung on to the side of the anode remote from the cathode, and is so connected that, by means of a switch, it may be put out of or into circuit, according to whether the current is passing from the anode to the cathode or not. The anodes are constructed of perforated iron or iron gauze, through which the electrolyte can freely pass, and if two cathodes be employed, the

anode is made double, and the basket filled with scrap zinc, or zinc plates connected with iron plates are suspended between them so that it may be put in or out of circuit as desired. Rotating anodes may be employed as described in Eng. Pat. 20,636, 1894 (this Journal, 1895, 871), and the cathodes are suspended between the anodes in the usual way, and are preferably kept in motion.—G. H. R.

*Metals, Impts. in the Electro-Deposition of.* [Jet Electrolyte.] J. C. Graham, London. Eng. Pat. 986, Jan. 14, 1896.

The electrolyte is contained in a tank placed from 1 to 2 ft. above the depositing bath, and is delivered against the face of the cathode in a jet. If the jet is delivered from a pipe  $\frac{3}{8}$  in. in diameter, placed  $1\frac{1}{2}$  in. from the cathode, and using as the electrolyte a nearly saturated solution of copper sulphate containing 5 oz. of commercial sulphuric acid to 1 lb. of water, a good deposit is obtained on the cathode over the area controlled by the jet, which is a circle of 5 in. in diameter, and the current density may be as high as 300 ampères per square foot. Beyond the controlled area the cathode is discoloured, and the deposit non-coherent, so that a sufficient number of jets must be employed to control the required cathode surface. The anode, which is copper, should have a surface eight or nine times greater than that of the cathode, and is preferably given a spiral corrugated or grid-like form, and the jets are arranged so as to play through it on to the cathodes. To prevent the formation of a non-coherent growth at the edges of the cathode, they are protected by shields of some insulating material, between which and the cathode face, the electrolyte flows.—G. H. R.

#### XII.—FATS, OILS, AND SOAP.

*Soap made with Carbon Tetrachloride [for Dry-Cleaning].* L. Axthelm. *Leipziger Färber- u. Zeugdrucker Zeit.* 45, 519.

A SUBSTANCE has long been sought, equal in cleansing properties to petroleum spirit, and possessing the advantage of non-inflammability. Such a substance is carbon tetrachloride, a colourless liquid (of sp. gr. 1.63, and boiling at 76 °C.) which is not only non-inflammable, but extinguishes a flame when poured upon it.

O. Schöning, of Bromberg, has succeeded in preparing a soap containing this substance, and the addition of this soap to petroleum spirit, in which it is readily soluble, greatly diminishes the inflammability of the latter; such a solution containing 10 grms. of soap per litre forms, it is stated, an excellent cleansing liquid.—R. B. B.

*Strophanthus Hispidus, Oil of the Seeds of.* A. Mjoen. *Arch. der Pharm.* 234, 283.

See under XXIV., page 72.

*Cleansing and Recovering Grease and Oil from Cotton and other Waste and Wool, A Method of and Apparatus for.* G. E. Wright, Nottingham, and W. Monk, Nottingham. Eng. Pat. 22,188, Nov. 21, 1895.

See under V., page 41.

*Degreasing and Cleansing Wool, Cotton Waste, and like Fibrous Material: Impts. in Apparatus for.* F. N. Turney, Nottingham. Eng. Pat. 1350, Jan. 20, 1896.

See under V., page 41.

*Cocoa or Coprah Oil, Manufacture of an Edible Fat from.* M. C. A. Ruffin, Paris. Eng. Pat. 1827, Jan. 25, 1896.

The oil is heated to its melting point (about 23° C.) and allowed to stand for 48 hours. A large proportion crystallises out and is separated from the liquid portion by means of a filter press, dry cakes being thus obtained amounting to about 45 per cent. of the mass treated. These cakes are then melted again and purified by treatment with lime, the lime emulsion being evaporated in a vacuum pan furnished with an agitator. The temperature must not be over 20–25 °C. The lime soap forms in granules, from which

the melted fat can be removed by pressure. The final product melts at 31° C.

To remove insoluble fatty acids from the fat thus prepared, the latter is melted, treated with quicklime, and the little water it contains evaporated off in a vacuum pan at a temperature of 20° to 25° C. The lime salts, together with the excess of quicklime, separate out completely as soon as all moisture has disappeared.—W. P. S.

**Raw Wool Fat, Impts. in Processes for Producing Chemical Combinations from.** [*Use of Alcoholic Ammonia.*] C. Schmidt, Magdeburg. Eng. Pat. 17,379, Aug. 6, 1896.

By treating raw wool fat with alcoholic ammonia at a temperature of 100° C., solution of the fat is obtained. On cooling, a portion is deposited consisting of ammonium salts of fatty acids, and fatty alcohols, whilst free fatty acid remains dissolved.

The separation of the deposit into nearly pure "sebaeic" fatty acid and fatty alcohols mixed with a little sebaeic acid, is carried out by treating the deposit with acetone, amyl alcohol (fusel oil), ether, chloroform, &c. The soaps are soluble with difficulty in these liquids, and by recrystallisation a product may be obtained, melting at 60° to 75° C., and consisting chiefly of sebaeic acids.

The impure fatty alcohols are clarified by boiling and by kneading with dilute alcohol and finally with water. They may also be purified by washing the soaps out of the solutions of the fatty alcohols, or by distillation. Mixtures of the fatty alcohols of wool-fat with water are used in pharmacy under the name of "lanoglycerin."—W. P. S.

**Soaps, An Impt. in the Manufacture of.** [*Admixture of Ground Oyster Shells.*] F. M. Sanders, Birmingham, and The Digby Patents Company, Birmingham. Eng. Pat. 19,257, Sept. 1, 1896.—W. P. S.

**Distilling Apparatus, Impts. in.** [*Glycerin Still, &c.*] J. V. Kaymbeke and W. F. Jobbins, both of Aurora, Kane Co., Ill. Eng. Pat. 20,982, Sept. 22, 1896.

Two distinct distilling plants are employed, each comprising a still, a series of separating drums, and one or more condensers. The necessary vacuum is produced in the apparatus by means of "a valved mechanical vacuum pump, common to both vessels, for maintaining a vacuum therein, and a second valved mechanical vacuum pump connected with and supplementing the action of the first vacuum pump." The crude material is placed in the first still and distilled by means of steam, &c., the vapours being condensed in the separating drums and condensers. The liquor condensed in the first drum consists of glycerin and impurities, and may be returned to the still; that in the succeeding drums is of sufficient purity to be used in the manufacture of dynamite, or it may be further purified by redistillation. The liquors condensed in the last separating drum and in the condensers, consist essentially of glycerin and water, and are collected in "sweet water" drums, from which they are ultimately removed and concentrated. The concentrated "sweet waters" are then introduced into the second still and distilled, as in the first apparatus, pure glycerin being collected in the intermediate separating drums, and water, with any glycerin which may be carried over, in the last drum and condenser. Collecting drums provided with suitable taps are arranged beneath the separating drums, to enable the contents of the latter to be drawn off without destroying the vacuum. The apparatus can also be used as a fractionating plant for separating glycol from the glycerin.—R. A.

### XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

#### (A.)—PIGMENTS, PAINTS.

##### PATENTS.

**Varnish, A Process of Manufacturing.** C. W. Jurany, Vienna. Eng. Pat. 23,202, Dec. 4, 1895.

A "PROCESS of manufacturing white varnish, consisting in mixing sulphide of zinc colour containing 40–70 per cent.

of ZnS and only 30 per cent. of BaS, in pure alcohol to paste form, the superfluous alcohol being pressed out or expelled by distillation." Coloured varnishes made by mixing similar colours with the preceding. The preceding products "are then dissolved in alcohol or benzene varnish."—F. H. L.

**White Lead for White-Lead Paint, Impts. relating to the Manufacture of [without Stove-drying].** C. D. Ismay, Newcastle-on-Tyne. Eng. Pat. 23,969, Dec. 14, 1895.

To avoid the necessity for stove-heating, and the dangers of handling the dry powder, white lead is often ground into oil while still wet with water; but it is found difficult to remove the last traces of the latter liquid, the presence of which is very detrimental to the finished material. According to the present invention, the wet pigment is mixed with the oil in a steam-jacketed covered pug-mill under reduced pressure and at a temperature of 65° to 120° C.; so that most of the water is evaporated during the process, the remainder being removed by conducting the final grinding on a roller mill having hollow rolls supplied with steam.

—F. H. L.

**Paint [Ferric Oxide], Impts. in the Production of.** C. Sullivan, Neath, South Wales. Eng. Pat. 2219, Jan. 30, 1896.

The waste (sulphuric) acid of tinworks is evaporated to dryness and the product furnaceed to yield the pigment for an oxide paint.—F. H. L.

#### (B.)—RESINS, VARNISHES.

**Sagapenum, Composition of.** Hoheuael. Arch. der Pharm. 1895, 33, 259.

This gum resin contains: essential oil, 5·8 per cent.; resin soluble in ether, 56·8; gum, 23·3; impurities, 10·6; and water, 3·5 per cent.

The essential oil, obtained by steam distillation, is easily soluble in ether, petroleum spirit, glacial acetic acid, chloroform, acetone, benzene; less readily in acetic ether and alcohol. The alcoholic solution, on the addition of hydrochloric acid, becomes violet, even in the cold; thus this reaction given by tincture of sagapenum is due to a constituent of the essential oil. The oil contains 9·7 per cent. of sulphur, valeric acid, and perhaps borneol valerate.

The resin, obtained by extracting with ether, distilling off the solvent, and then driving off the essential oil with steam, with the exception of 0·11 per cent. of free umbelliferone, is entirely composed of umbelliferone (15·7 per cent.) combined with the alcohol,  $C_{21}H_{32}O_4(OH)$ , sagaresinotannol. This ester, treated with nitric acid, gives oxypicric and not camphoric acid. The gum has not been examined.

—A. C. W.

**Copal, Zanzibar.** A. Stephan. Pharm. J. 1896, 57, 525.

The author examined specimens of this variety of copal sent from Bagamoyo, in East Africa. The copal, finely powdered, melts at about 140° C.; it is slowly but completely soluble in alcohol; benzene, chloroform, and glacial acetic acid dissolve about 30 per cent., ether about 34 per cent., and petroleum spirit and carbon bisulphide about 10 per cent. When boiled with alcohol, the resin caked and only a slight proportion dissolved, but by repeated digestion with alcohol, it could be brought entirely into solution and then reprecipitated with water. The resin, thus purified, was more soluble in the menstrua previously mentioned, and was also soluble in very dilute boiling potash solution (0·1 per cent.). It appeared to consist of resin-acids, the principal of which, constituting about 80 per cent. of the resin, was called trachylic acid. This acid was obtained with difficulty in minute spherocrystalline masses, melting at 168° C. From it the potassium, copper, and iron salts were prepared. A second acid, called isotrachylic acid, present to the extent of about 4 per cent., was also obtained. These two acids, together with about 6 per cent. of  $\alpha$ -copal resin and  $\beta$ -copal resin, a bitter principle and volatile oil, were the only constituents the author succeeded in separating.

—A. S.

## (C).—INDIA-RUBBER, &amp;c.

*Balata Industry of Dutch Guiana.* J. Soc. Arts. 44, 908.

BALATA is obtained from the bullet or bully tree, *Mimusops Balata*, a large forest tree of the order Sapotaceæ. The tree reaches maturity at a height of 120 ft., with usually a large spreading head, a trunk 60 to 70 ft. high, and 4 to 5 ft. in diameter; but a tree with a trunk above about 30 ins. in thickness is generally not considered worth "bleeding." Balata commands a higher price than gutta-percha—in fact, it is used as a superior variety thereof. Nevertheless some of its physical properties show that balata is distinctly different from gutta-percha, though its chemical composition is probably quite identical therewith, as also with that of caoutchouc. A very marked difference between gutta-percha and balata is to be found in the fact that whereas the former, when exposed to light and air, soon becomes altered on the surface and changed into a brittle resinous substance, the latter is but slowly acted on under the conditions named.—C. O. W.

## PATENTS.

*Gutta-Percha, Improved Process of Obtaining and Purifying.* E. Sérullas and F. Mourant, Suresnes, France. Eng. Pat. 654, Jan. 9, 1896.

THE raw material is first purified by treatment with hot or cold water and alkali (preferably under pressure), and then is extracted with a solvent, such as toluene. Instead of removing this by distillation, however, the gutta-percha is precipitated, either by the addition of acetone or by lowering the temperature of the solution, the deposit being finally washed with acetone in a filter press. It is claimed that, whilst distillation or evaporation of the solvent injures the product, separation of the latter from the solvent by precipitation preserves all its good qualities whilst eliminating all other resinous matters, such as chlorophyll and the like.

—F. H. L.

*Waterproof Fabrics, Impts. in the Printing of, and Apparatus therefor.* J. Berry, Salford. Eng. Pat. 1375, Jan. 20, 1896.

See under VI., page 42.

*Vulcanising Apparatus, An Impt. in.* P. J. Davis, Rochester, Monroe Co., N.Y. Eng. Pat. 20,959, Sept. 22, 1896.

THE object of the invention is to produce a vulcanising apparatus in which the fastening devices for the cover of the retort are easily managed and readily adjustable.

## XIV.—TANNING, LEATHER, GLUE, SIZE.

*Fermentation Phenomena in Tan Liquors.* F. Andreasch, Imp. Research Laboratory, Vienna. Ger. Gerber, 21, 506, 22, 513, 15.

THE author divides the third group (see this Journal, 1896, 611, final paragraph) into three sub-divisions: 1. Alcoholic ferments. 2. Acetic acid ferments. 3. Lactic acid ferments.

As he confines his researches to this group, we may consider his work in two parts: (1) General considerations and results of research in the above three sub-divisions; and (2) Details of researches of the fermentation of typical tan liquors.

**Alcoholic Ferments.**—The alcoholic fermentation in tan liquors is produced by various yeasts, principally bottom-fermentation species. Other yeasts form a film on the surface of standing liquors. Some concentrated extracts, such as pine-bark extract, are fermented by yeasts, with evolution of CO<sub>2</sub>. Myrabolan liquors mashed cold contain much finely divided material and an easily fermentable sugar from the myrabolan rind; in these the alcoholic fermentation is generally marked. The constitution of the glucosides, which form a large part of the non-tannin of the liquors, is little known. Dextrose, however, is found, and this splits up into alcohol and CO<sub>2</sub>. The amount of alcohol is nearly always under 2 per cent.,

but in abnormal cases may reach 3 per cent. In the majority of cases the alcohol is changed into acetic acid almost as fast as produced.

The following yeasts have been found in tan liquors:—

*Saccharomyces pastorianus* (Hansen), *S. ellipsoideus* H. (Hansen), *S. apiculatus* (Reess), *S. ellipsoideus* L. (Hansen), and *S. acidi lactici* (Grottenfeld).

The two first and most frequently occurring, which are disease organisms in beer, are the principal cause of alcoholic fermentation in the tannery.

In addition the following fungi occur—Rose-coloured torula and orange-yellow torula.

These form small quantities of alcohol, but are only of botanical interest; the orange-yellow torula was first isolated from old mixed liquors by the author.

2. **Acetic Acid Fermentation.**—The author has found no organisms in tan liquors capable of fermenting carbohydrates direct to acetic acid. Such fermentations are theoretically possible, but can only be considered as exceptional. In the very numerous tan liquors examined, alcohol was always the primary product, this being oxidised to acetic acid. The chief organisms causing this oxidation are *Bacterium aceti* (Hansen), *B. Pasteurianum* (Hansen). The third species, *B. Kützingerianum*, he has not hitherto found in tan liquors.

The two first differ in their behaviour toward iodine solution. *B. Pasteurianum* is stained blue by iodine; *B. aceti* only yellow. Their action on nutrient solutions containing small quantities of alcohol is about equal.

Pellicles of *B. aceti* and *B. Pasteurianum* are not often seen on tan liquors, being broken up by the moving of the liquor and the raising of the skins; their formation is also interfered with by *Saccharomyces* and various forms of mycoderma, which, at the usual tannery temperature, develop much more quickly than acetic acid bacteria. The acetic fermentation does not go on at a less temperature than 12° C. It is possible by sowing the requisite organisms in the liquor to induce the proper acidity, which is sometimes prevented by the absence of alcoholic ferments. In a tan liquor 20 months old, containing a normal amount of tannin, and non-tannin, and acidity, but no acetic acid, a bacteriological examination showed the absence of alcoholic and acetic ferments, and it was evident that the lactic organisms had ceased to grow for want of albuminous material. The liquor, however, contained abundant mycoderma and kefir organisms; milk inoculated from it underwent a vigorous fermentation with copious evolution of CO<sub>2</sub>. Fresh tan liquor inoculated from the same, developed only mycoderma; no acetic acid was formed for want of alcohol, though doubtless the spores of acetic bacteria were present. This is frequently the case in practice, and the addition of sour liquor to a fresh tannin infusion, instead of souring it, will sometimes actually prevent the souring.

Amongst the fungi found in the liquors, the various forms of mycoderma are of importance here, as they not only decompose the alcohol, but also the acetic acid; they ferment dextrose, levulose, invert sugar, and cane sugar, using albuminous bodies and even simple ammonia compounds as nitrogenous nutrient material, whereas the true yeasts draw their nitrogen from amides and peptones, and only assimilate albumins with difficulty. The CO<sub>2</sub> produced by the mycoderma has only a very slight swelling effect on the hide fibres. The chief cause of injury is that these organisms overgrow most others in a sweet liquor, and hinder or prevent the acetic fermentation; the most favourable temperature for their growth is 12°–20° C. whereas the optimum for *B. Aceti* is 33°–37°.

As showing the rapidity of development of mycoderma, the author has observed the formation of a thick pellicle in a single summer night on the weak liquors of an American sole-leather tannery where the hides are moved during the day by "rockers." *B. aceti* grows best in a solution containing 2.5 per cent. of alcohol and 1.5 per cent. of acetic acid, as well as the usual nutrient materials. No tan liquors, of course, contain so large a quantity of acid; but acid is necessary for the growth of the organism, which grows with difficulty in a neutral medium. The tanner cannot regulate the acetic fermentation of his liquors like the vinegar manufacturer, but by approaching as near as possible to the best conditions for the growth of the

bacteria, he may greatly influence the fermentations to his advantage.

Summing up the processes connected with the acetic acid fermentation of tan liquors, we have:—

(1.) Action of *Saccharomyces*.—Sugars fermented to alcohol and CO<sub>2</sub>.

(2.) Action of acetic bacteria.—Alcohol fermented to acetic acid and water.

(3.) Action of *Mycoderma*.—Alcohol and acetic acid split up directly into CO<sub>2</sub> and water.

**Lactic acid fermentation** is somewhat more complicated than acetic acid fermentation, and continues after the cessation of the latter.

A large number of lactic ferments occur in tan liquors, some of which set up a pure fermentation; others cause, in addition to the production of lactic acid, further changes, which may be considered as diseases of the liquors.

In the lactic acid fermentation of milk, the sugar is decomposed with evolution of a little gas, the casein is coagulated by the acid formed, and in the case of a pure fermentation, no further change takes place. In tan liquors, the sugars are also decomposed with formation of lactic acid, but the fermentation is complicated by the presence of yeasts and acetic bacteria, besides other organisms.

Certain lactic bacteria cause the liquors to become slimy—an evil which delays the tanning process by making diffusion slower. The age of the liquors, their concentration, the kind of tannin, and the condition of the hides, determine the species of lactic organism present.

In the same tannery different species of lactic bacteria were found in the different liquors, and mostly in a state of comparative purity.

In place of the casein in milk, the peptones formed from the hide substance by other bacteria previously mentioned (see this Journal, 1896, 911), and in some cases the gelatinous substance of the hide itself, supply the nitrogenous food for the bacteria. The spontaneous lactic acid fermentation as it takes place in milk is of most importance; and if a large amount of acidity be required in the liquors, such organisms should be introduced as produce acid rapidly and are not influenced by the presence of the acetic acid previously formed.

The list of organisms given below are those which the author has found in tan liquors, though there are doubtless other species he has not met with. There are also varieties of these types.

He divides them into four groups:—

A. Lactic acid bacteria of milk.

*Bacillus acidi lactici* (Hueppe).

*Bacterium acidi lactici* (Grottenfeldt).

*Bacterium lactis acidi* (Marpmann).

All three species may occur in normal tan liquors.

B. Lactic acid bacteria which cause the ripening of cheese.

*Bacillus* XIX. (Adametz) from old liquors containing much peptone. (Found twice.)

*Bacillus a* (Freudenreich), or a variety of the same.

Lactic acid—forming tyrothrix (Duclaux) from very old sole-leather liquors, and a first weak liquor ("Stinkfarbe").

C. Specific bacteria of lactic fermentation of tan liquors, isolated from tan liquors by plate cultures with milk-serum gelatin, and cultivated by Hansen's method.

Lactic acid bacterium of tan liquors I.

Lactic acid bacterium of tan liquors II.

Lactic acid bacilli of tan liquors *a* and *b*.

Lactic acid micrococci of tan liquors *a*.

D. Lactic acid yeasts.

*Saccharomyces acidi lactici* (Grottenfeldt).

Lactic acid yeasts of tan liquors *a*, *B*, *γ*.

All three forms are of equal activity, and were first cultivated from old pine-bark liquors.

The following accessory lactic acid bacteria also occur:—

*Bacterium acidi lactici* (Pasteur), identified from the description of Bontroux, Duclaux, and Zopf; found in pure myrabolans liquor after undergoing alcoholic fermentation.

*Gas-forming, liquefying lactic acid bacillus*, from upper leather weak liquors after the dung bate.

*Bacillus lactis viscosus* (Adametz), causes slimy orropy liquors, repeatedly isolated from the liquors of tanneries, using river water in which the Adametz bacillus was found.

A more exact description of the new lactic bacteria isolated by the author, *Bacterium* 1 and 2. *Bacillus a* and *B*, and Micrococcus *a*, will be given in another place.

Groups A., C., and D. may be considered as normal producers of lactic fermentation; Group B., especially Tyrothrix, generally occurs in bad liquors, containing much albuminous matter in solution. The presence of any organisms of Group B. may be regarded as an indication that the liquors are going wrong.

Group A. does not grow so well in tan liquors as in milk; on the other hand, the yeasts of Group D. are the principal causes of sound lactic fermentation of tan liquors, no doubt owing to the fact that the presence of large amounts of tannin does not hinder their development. In general, one or two species preponderate in a given liquor, depending on its character (upper or sole, old or new liquor) and on the amount of undecomposed sugars and nitrogenous compounds.

The hides, owing to their nitrogenous contents, have a far greater influence on the lactic than on the acetic fermentation, where only small quantities of nitrogenous nutriment are required. The author finds that the lactic acid bacteria draw upon the hide substance for their nitrogen, either in the unaltered form of the intercellular substance, or the same peptonized by putrefactive bacteria.

The influence of albuminoids on the activity of the lactic acid yeasts and bacteria explains the well-known fact, that in old liquors where such materials are present, the amount of lactic acid is greater, and it also explains why the maximum formation of lactic acid in tan liquors occurs much later than in milk, because the necessary nutrient materials are not present in so large amount, but are supplied gradually to the liquor. For the same reason, the addition of a drop of sour milk to sterile neutral tannin infusion, sets up lactic fermentation with difficulty, but if ammonium salts and phosphates be added, the fermentation proceeds rapidly.

The most favourable temperature for lactic fermentation lies between 30° and 35°, but it can also go on at 12°. This optimum is naturally never reached in tan pits, but in summer these bacteria will frequently overcome the other ferments, producing then a much purer lactic fermentation. Liquors prepared in summer contain a much greater number of lactic organisms than other bacteria, as may be shown by comparing sour bark liquors from layer pits (Versetzgruben) which have often stood for a whole year exposed to great variations of temperature, with upper leather weak liquors which are only used in summer for a few weeks. The presence of phosphates is very favourable to lactic fermentation, but they are not present in such quantity as in milk, except in certain fruit tannins, Myrabolans, Dividivi, and Algarobilla, all of which easily undergo lactic fermentation.

Unless the acid produced be neutralised, its formation ceases when the amount of acid reaches 0.6—0.8 per cent. The lime in the hides neutralises a portion of the acid, and the hide fibres take up and hold a certain amount. The presence of the hide is necessary whether, like Timpe, we regard the albuminous bodies as merely neutralising the acid, or, like Hueppe, as food stuffs for the bacteria; at any rate, the hides materially assist the lactic fermentation. The amount of tannin also influences it, a high amount of tannin rendering the fermentation slower, but never stopping it. The yeasts are not affected by the tannin, and can grow even in thick extract of 25° B. The influence of foreign organisms on the lactic fermentation of tan liquors has yet to be studied exactly, but the author finds that when once the lactic acid is produced, it protects the liquors from infection by such organisms.

After acetic and lactic acids, carbonic acid is quantitatively the most important product of fermentation, being produced both by *Saccharomyces* and many species of bacteria. The gas both de-limes and swells the hides. The lactic bacteria only produce a small amount of CO<sub>2</sub>. The amount of the gas present depends on the temperature of the

liquors, the moving of the hides assists its escape, so that at any given time the amount dissolved in the liquors is usually small (see tables); in practice, therefore, this product need not be considered.

*Propionic acid* has also been found in small quantities in tan liquors (Wladika, Zur Kenntniss d. Org. Säuren in Fichtenbrühen. Der Gerber 16, 28). It occurs as a by-product of alcoholic fermentation, by the action of yeasts on the glycerin formed, and in some cases by direct fermentation of the calcium salts of lactic and malic acids by bacteria (Fitz and Duclaux).

Malic acid exists in large quantities in some fruit tannins and Wladika has found it in pine bark liquors. The formation of propionic acid in tan liquors is only of theoretical interest.

**Butyric fermentation** is in most cases of even less importance than propionic. The various bacteria causing it are chiefly anaerobic, and require a fairly high temperature for their proper development (40°). Their principal nutrient material is calcium lactate, so that except in such old liquors as have been used for de-liming, the conditions of growth, are not favourable. Besides which, the aeration of the liquors by the regular shifting of the hides further hinders their growth. In a large number of liquors examined, (*Clostridium Butyricum* (Prazmowski) was only twice found.

In any case butyric acid has not the importance for the tanner Lietzmann assumes in his "Herstellung der Leder."

**Viscous or ropy fermentation** often occurs along with the lactic fermentation, and may also be caused by peptonising bacteria. The liquors become thick and in bad cases may be drawn up by the hand in long threads. Slight cases much hinder the proper diffusion of tannin in the liquors.

From ropy liquors examined, *B. lactis viscosus* (Adametz) and *B. viscosus* (Frankland) were twice isolated. In some cases the ropiness appeared to be produced by *B. mesentericus fuscus* (Hueppe), other liquors from which no slime organisms could be isolated produced ropy fermentation in tannin infusions containing peptones, but in pure fresh tan liquors under exactly similar conditions of temperature, &c., no ropy fermentation was produced. The author has shown that *B. viscosus* (Frankland) only produces ropy fermentation in materials containing peptones; this naturally applies to tan liquors.

**Origin of the Ferments and the Infection of the Liquors.**—The chief sources are the water used, the hides, the tanning materials, and the air. The water organisms are introduced directly in the preparation of the liquors and also indirectly with the hides; with the latter also are brought in the various bate organisms, the previous washing by no means freeing them from bacteria. At the same time the special dung and urine bacteria do not attain to any great development in the liquors. Those found have been already mentioned (*vide* this Journal, 1896, 910—911).

In order to determine what micro-organisms the tanning materials themselves contained, a bacteriological examination of fresh pine and oak barks and myrabolans (as fresh as possible) was made. The result was that lactic and acetic organisms were only sporadic, and it was doubtful whether the spores of those found did not come from the air of the tannery from which the material was taken.

In infusions of the above materials made with sterile water, no sensible acid fermentation took place during periods of 2, 4, 8, 20, and 30 days, but in each case a weak alcoholic fermentation was set up by the saccharomycetes which were always present.

The following organisms were found on barks:—*Micrococcus flavus liquefaciens*, *M. versicolor*, *Bacillus ochraceus*, the potato bacillus, various species of *Sarcina*, and some gelatin liquefying bacteria. The bacteria were cultivated from fresh bark and also from bark a year old, in the latter no moulds were found.

These results are of importance as showing that the growing of the liquors cannot be caused by bacteria present in the barks, &c. used; on the other hand, the alcoholic fermentation set up by the saccharomycetes, because they are found in large numbers on the bark, leaf and fruit tannins.

The bacteriological examination of the air of tanneries was made by drawing a measured volume through tubes coated with sterile petone-, wort-, or milk-serum-gelatin; dishes of these materials were also allowed to stand in the tannery for different periods of time.

All the organisms previously arranged in groups were found (see this Journal, 1896, 911). Yeasts and moulds were most abundant, then followed putrefactive, acetic, and lactic bacteria. The number of germs and species was far larger in tanneries working on the old system owing to the heaps of bark and the dust. Where liquors only were used the air was much freer from micro-organisms.

The infection of the liquors takes place naturally from material left clinging to the sides of the pits, &c., for liquors made from hot extracts ferment in much the same manner as those prepared in the old way. By a proper choice of inoculating material very certain results may be obtained.—J. T. W.

*Tanning, The Use of Mangrove Bark for.* M. Gürke. Notizbl. d. botan. Gart. u. Mus. zu. Berlin, 1896, 1, 169.

The author recommends that, notwithstanding the non-success of previous attempts to introduce the mangrove bark into Europe for tanning purposes, fresh trials should be made with this bark, which might now be procured from the German East African colonies.—I. S.

## PATENTS.

*Skins and Hides, A Novel and Quick Process in Preparing and making them into Buff or Oil Leather in less than 24 Hours.* H. Riches and W. G. Riches, Godalming. Eng. Pat. 16,865, Sept. 10, 1895.

The skins, after previous treatment in the lime pits, are bated or drenched in a bath containing a 1 per cent. solution of ammonium sulphide or sodium hyposulphite (thiosulphate). This process takes one or more hours, according to the thickness of the skins. The skins may, after drying and pressing, be milled with cod oil, sod oil, or neats-foot oil, or white fats or greases, and afterwards washed in the usual way or with ammonium carbonate.

—W. P. S.

*Manure, Process for rendering Waste Leather soluble and applicable as a.* J. Hudson, London. Eng. Pat. 289, Jan. 4, 1896.

See under XV., page 55.

## XV.—MANURES, Etc.

### PATENTS.

*Blood and Slag Manure, Process for the Production of.* W. Barclay, Newcastle-on-Tyne. Eng. Pat. 22,160, Nov. 21, 1895.

DISINTEGRATED blast furnace slag, either produced from ordinary iron ore, or hematite ore, or Normanby patent slag, is mixed with fresh, coagulated, dried, or dissolved dried blood, and the mixture is dried at between 14° C. and 37° C. or left to dry naturally, and can then be applied to the soil for manurial purposes.—D. A. L.

*Superphosphate and the like, Impts. in Apparatus for Drying.* J. Y. Johnson, London. From the Verein Chemischer Fabriken, Mannheim. Eng. Pat. 22,713, Nov. 27, 1895.

A NUMBER of slightly inclined sieves or gratings, made of barbed wire or perforated metal plates, in any case preferably provided on the upper surface with small vertical spikes, are arranged one above another in a shaft furnace, drying oven, or kiln, and are connected with a shaking mechanism. Steam coils or other means are used for heating and the material is charged in at the top; the lumps are retained by the spikes, until disintegrated and dry, the fine falling through the sieves.—D. A. L.

*Manure, Process for rendering Waste Leather soluble and applicable as a.* J. Hudson, London. Eng. Pat. 289, Jan. 4, 1896.

Waste leather is first thoroughly soaked with water containing harm or other ferment, then spread in successive layers over a floor until fermentation is set up. The latter may be started by employing a portion of leather already fermented. When fermentation is complete, the material may be used as a manure direct, or may be dried or pulverised before application.—D. A. L.

*Ground Slags intended for Use as Fertilisers, Impts. in the Treatment of.* C. H. and A. W. Langdale, Newcastle-on-Tyne. Eng. Pat. 22,666, Oct. 13, 1896.

From 2 to 20, preferably, 8 per cent. of a saturated solution of magnesium salts in brine, is mixed with the ground phosphatic basic slags intended for use as fertilisers.

—D. A. L.

## XVI.—SUGAR, STARCH, GUM, Etc.

*Sugar Juice, Observations on the Boiling of.* J. Curim. Zeits. für Zuckerind. in Böhmen, 1896, 25, 176—183.

HAVING occasion to determine the boiling point of various sugar solutions, the author became aware of the magnitude of the error, especially with a good vacuum, when the temperature is measured merely by the usual vacuum gauge without regard to the atmospheric pressure. Temperatures given in Regnault's table corresponding to the vacuum in the apparatus, if taken without regard to the atmospheric pressure, may render the results of a test quite useless.

From the table following, it appears that with a vacuum of 650 mm., and an atmospheric pressure of 720 mm., the error amounts to 9° C. (OZ. 1894, 985.)

Vacuum in Cm.	Error in C. with an Atmospheric Pressure of			
	750 mm.	740 mm.	730 mm.	720 mm.
70	3.4	7.5	12.6	17.9
65	1.9	4.0	6.1	9.0
60	1.1	2.9	4.1	6.2
55	1.1	2.2	3.4	4.6
50	0.9	1.8	2.8	3.8
45	0.8	1.6	2.4	3.3
40	0.7	1.4	2.15	2.9
35	0.6	1.2	1.8	2.6
30	0.56	1.1	1.7	2.3
25	0.51	1.0	1.52	2.1
20	0.47	0.95	1.4	2.0
15	0.44	0.9	1.34	1.8
10	0.42	0.84	1.26	1.7
5	0.40	0.8	1.2	1.6
0	0.35	0.7	1.1	1.5

After establishing this fact the author endeavoured to find the relation between the vacuum and temperature in the vacuum space (above the juice) during the boiling of sugar juice, employing for this purpose a cylindrical syrup pan with steam coils. To measure the vacuum he used his closed mercury vacuum gauge which is not exposed to the influence of the atmospheric pressure (Zeits. Zuckerind. Böhmen, 1893—1894, 541). This and a tested thermometer were placed at the highest point of the pan immediately under the cover.

The results are collected in the table below:—

Space above the Juice.			Temperature of Juice, B° C.		Density of the Juice ° Balling.	Differences of Temperature.		
Vacuum Cm.	Corresponding Temperature.	Actual Temperature.	In the Upper Layer.	In the Lower Layer.		$\Delta_1 = B - A.$	$\Delta_2 = B - A_1$	$d_2 = A_1 - A.$
	A°.	A <sub>1</sub> °.						
66.2	51.3	58.0	65.5	65.5	83.0	14.2	7.5	6.7

(2) 50.2	72.5	63.0	80.2	80.5	..	7.7	17.2	- 9.5
45.2	76.7	62.0	83.8	83.4	..	7.9	21.8	-14.7
40.1	80.4	62.0	86.8	86.5	..	6.4	24.8	-18.4

Several other similar tables are given in the paper. From the foregoing table we see that the first reading was made at the moment the syrup was at a concentration of 83° Balling, the vacuum being 66.2 cm.

The thermometer  $A_1$  showed 58° C., although, according to the tables, this vacuum corresponds to a temperature of 51.3° C. The thermometer  $A_1$  shows therefore the actual temperature, which is higher than the calculated; the difference  $d_2 = A_1 - A$  amounts to 6.7° C.

This difference increases the thicker the syrup becomes, and reaches 13.6° C. at a density of 89.8° Balling. The figures given, relate to regular boiling without the drawing in of juice.

On the other hand, the figures under (2) were taken after the air-pump was shut off and stopped, and have no relation to the boiling, but were introduced merely as of interest. They show that during the warming of the syrup, while its temperature rises, the space above the juice becomes saturated by the escaping vapour, so that the vacuum falls and the temperature  $A_1$  rises, or the difference  $d_2$  quickly becomes negative. Another table showed that even during the introduction of fresh juice,  $d_2$  remained positive; therefore, in all cases during the boiling of syrups  $A_1$  is greater than  $A$ .

The author proceeds to show that this difference is not due to froth or waves of syrup coming into contact with the

thermometer, which would cause irregular variations, but to small particles of syrup carried away with the vapour, and he is following up the relation between the difference  $d_2$  and the loss of sugar during boiling.

In conclusion, columns 4 and 5 show that the temperature in all layers of the boiling juice is the same. Although Jelínek (Zeits. 1890—1891, 91) arrived at the same result, yet it is often stated, especially in foreign literature, that the lower layers are hotter in proportion to the pressure due to the column of syrup. Calculation shows that with a vacuum of 66 cm. and a height of 50 cm. between the two thermometers, a syrup of sp. gr. 1.45 should show a difference of 8.8° C. if this were the case. No differences greater than 0.5° C. were found, and he concludes that the column of syrup has no influence on the boiling point of the lower layers.—L. J. de W.

*Masseccutes, Critical Observations on the different Method of Working.* H. Claassen. Bull. de l'Assoc. des Chimistes de Sucre et de Dist. 1896, 14, 447—452.

The author is of opinion that the value of a process for treating masseccutes depends entirely upon the method of boiling. He has investigated the composition of the mother-liquors adhering to the crystals during the various stages of boiling, and considers that the coefficient of supersaturation should be regarded as the criterion of any boiling process.

The Bock, Kutter, Manoury, Huch, and other methods of treating massecuites are discussed; and it is insisted that, whatever the process, the following conditions are necessary:—1. A regular and slow boiling to be carried out subsequent to the last addition of syrup; the latter should not be saturated at the temperature of ebullition. 2. The massecuite to be concentrated until the syrup adhering to the crystals is not too supersaturated; the coefficient advised is 1.2 to 1.3. 3. The massecuite to be run into suitable mixers provided with heating and refrigerating arrangements. The chilling must be so conducted that the coefficient of supersaturation of the mother-liquors is about 1.1. 4. The boiling or mixing to be discontinued when the purity of the syrup has fallen to 70; this value, however, should be higher for strongly coloured massecuites.

—J. L. B.

*Raw Sugars; Decrease of Alkalinity.* O. Mittelstaedt. Bull. de l'Assoc. des Chimistes de Sucre et de Dist., 1896, 14, 436—447.

NEW raw sugars which have been derived from juices mixed with sulphurous acid contain alkaline sulphites, hyposulphites (thio-sulphates), and probably also polythionates. The formation of these salts arises from incompletely burnt sulphur, or by a too rapid passage of gas, whereby particles of sulphur pass into the strongly alkaline juice. During storage the sulphites are gradually oxidised to sulphates; no diminution of alkalinity can, however, result. The hyposulphites (thio-sulphates) and polythionates, on the other hand, are decomposed into sulphurous acid and sulphur, and then to sulphuric acid and sulphur; these products of oxidation destroying the alkalis.—J. L. B.

*Sugar; Action of Sulphurous Anhydride on.* W. Grundmann. Bull. de l'Assoc. des Chimistes de Sucre et de Dist., 1896, 14, 431—440.

THE author has carried out an extensive series of experiments on the action, under varying conditions, of sulphurous acid on cane-sugar solutions. He finds in some cases that juices, which before sulphuration reduced Fehling's solution, failed to do so afterwards; this is probably due to the sulphurous acid modifying or destroying certain reducing substances present. It was also found possible to leave a saturated solution of sugar containing a slight excess of sulphurous acid for several weeks without any inversion taking place. On increasing the acidity, the solutions underwent inversion according to the amount of acid which they contained. The quantity of acid required for decoloration is at all temperatures lower than that necessary for inversion. Acidity increases more rapidly in cold than in hot juices. Up to a certain limit molasses are, however, an exception. These latter can moreover absorb a greater amount of sulphurous acid owing to the salts they contain. Acid juices invariably undergo inversion when boiled. The presence of ammonia appears to hinder inversion.—J. L. B.

*Gum Ammoniac [Ammoniacum], Composition of.* H. Luz. Arch. der Pharm., 1895, 33, 540.

THIS gum has the following composition:—Resin soluble in ether, 65.0 per cent.; matters soluble in water (gum), 22.7; matters insoluble in water, 3.5; and water, 1.4 per cent. together with a small quantity of an essential oil, which has not been completely examined, but which is distinguished from the essential oils of sagapenum and costifera by not containing sulphur.

The resin varies in colour from a golden to a reddish-yellow, is soluble in alcohol, carbon bisulphide, chloroform, and glacial acetic acid; it is not completely soluble in acids; its ethereal solution and aqueous extract contain small quantities of salicylic acid, to which is due the violet coloration with ferric chloride, given by aqueous decoctions of the gum. By shaking the ethereal solution of the resin with potash, the resin is separated into an acid resin soluble in the alkali, and a neutral resin remaining in the ether; neither of the two contains sulphur. The acid resin saponified by potash yields salicylic acid and small quantities of valeric and butyric acids, and an alcohol, ammonio-resinotannol,  $C_{11}H_{12}O_2(OH)$ , isomeric with galbaretinotannol.

The gum, when purified, contains 1.2 per cent. of lime, and in this respect resembles gum arabic.—A. C. W.

#### PATENTS.

*Extracting Sugars [Use of Lead Oxide], Impts. in, from its Solutions.* A. Wohl. Charlottenburg, Germany. Eng. Pat. 22,859, Nov. 29, 1895.

YELLOW lead oxide (PbO) is used for extracting sugar from molasses or other salty after-products, with the addition of alkaline hydrates or carbonates to decrease the reaction between the lead oxide and the salt-like non-saccharine bodies present. The lead saccharate is washed with water at gradually increasing temperatures. The last traces of lead are removed from the sugar solution, after carbonating, by treatment with calcium hydroxide and carbonic acid, and filtering hot, with or without subsequent treatment with animal charcoal or very small quantities of magnesium powder.

The lead oxide is regenerated by heating the precipitate from the saturation stage, first at a low temperature with access of air, and then to 600° C., air being excluded. An alkaline earth in the form of a hydrate or carbonate may be added to the precipitate before burning, or it may be previously boiled with a dilute alkaline solution.

—L. J. de W.

*Centrifugal Machines, Impts. in, for Drying Sugar and other Granular Substances.* W. P. Abell, Essequibo. Eng. Pat. 22,900, Nov. 29, 1895.

THE perforated basket is formed of two perforated cones placed base to base, with a permanent opening between their bases, and a casing, which encircles the basket, is adapted to revolve therewith, and has an independent movement in respect thereto, and a closing device or door secured to the casing and adapted to close the opening between the edges of the cones.

After the basket has received the regulated charge of massecuite, it is revolved for a length of time, previously decided upon as necessary to dry the quantity of massecuite dealt with. During this revolution the granular substances are retained in the basket by the perforated cones and door, while the liquids are driven, by centrifugal force, either directly into the fixed molasses casing or into the director or revolving molasses casing, which also delivers them into the fixed casing. When the massecuite is

sufficiently dry, a sleeve is lowered, and, with it, the molasses director and the door, whereby the dry sugar is discharged by centrifugal force through the permanent opening on to the intumed edge of the fixed dry sugar casing, and is deflected through the central outlet.

—L. J. de W.

*By-Products of Sugar Works and Sugar Refineries, An Improved Process for Treating the.* M. Sachs, Kiew, Russia. Eng. Pat. 1104, Jan. 16, 1896.

The process claimed is the boiling of by-products for crystals, along with repeated additions, in a vacuum-pan, or other like evaporating apparatus, and keeping the products to be supplied to the apparatus at a higher temperature than that of the apparatus.

The second product is boiled to grain instead of to string-proof, and half of the contents is dropped as soon as the grain is sufficiently large, and the quantity drawn off is replaced by repeated supplies of the same product, and the whole mass is kept boiling. The withdrawal and replenishing of the product is, preferably, continuous, and is maintained until a secondary crystallisation of a mealy or floury character appears, when the whole is drawn off. The vessels thus filled are kept at a temperature of 88° F. or higher for about six days to complete the crystallisation.

—L. J. de W.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*Brewers' Yeasts, Contribution to the Study of Several.* E. Boulanger. Ann. Inst. Pasteur, Oct. 1896. La Bière, 4, [12], 179—182.

THE yeasts selected for the investigations detailed were: Neunkirchen, Bass, Copenhagen 48, Hofbrau, Weihestephan, Loewenbrau, Riga X, Froberg, Saaz, and a high-fermentation yeast from Brussels.

The *Brussels yeast* was killed by a temperature of 55° C.; it yielded no spores; droplet cultures on gelatin liquefied the medium in 3½ months.

The *Froberg* (low-fermentation type) succumbed at 50° C.; liquefied gelatin in 2 months; produced no spores.

The *Neunkirchen* (low-fermentation) forms groups adhering to the sides of the fermenting vessel and clarifies quickly. It dies at about 50° C., and produces spores in about 240 hours on plaster and in 15 days in Liebig bouillon. The colonies from droplet cultures spread out considerably, but scarcely liquefy the gelatin in 6 months.

The *Bass yeast* gave no spores, died at 55°, and liquefied gelatin in 5 months.

The *Copenhagen 48* (low-fermentation) was non-sporiferous, perished at 55° C., and liquefied gelatin in 3 months.

The *Hofbrau* (low-fermentation) succumbed at about 50° C., and gave no spores. The droplet colonies spread considerably, forming "craters," but took 4 months to liquefy gelatin.

The *Weihestephan* (low-fermentation) yeast furnished no spores, and died at 55° C. Its colonies from droplet cultures were of a clear reddish-grey colour, and liquefied the gelatin in 4½ months.

The *Saaz yeast* (high-fermentation type) was non-sporiferous, and perished at 50° C. After 4 months, a slight liquefaction of the gelatin was effected.

The *Loewenbrau* (low-fermentation) settled down in large granules. In the other particulars it resembled the preceding, but liquefaction had barely set in at the end of 6 months.

The *Riga X* (a low-fermentation Russian yeast) perished at 55° C., yielded no spores, and liquefied the gelatin after 4 months.

Two cases of degeneration were noticed, the Bass and Neunkirchen yeasts being directly descended from yeasts which in 1889 were sporiferous, and at that time able to withstand a temperature of 60° C. On the other hand, some of the Bass yeast spores, kept the same length of time, preserved their spore-producing power, although in respect of resistance to high temperature they had degenerated to the extent of 5° C.

In the attenuation tests the high-fermentation yeasts worked at 18° in the primary and 12° in the secondary fermentation, the process lasting 35 days, whilst the low-fermentation types worked at 8° for 20 days, the secondary fermentation lasting 2½ months at 5°. The greatest attenuation was produced by the Froberg (76·5), Neunkirchen (76·3), and Weihestephan (76·4), and the lowest by the Bass (67·4) and Saaz (66·9) yeasts. The residual maltose was greater with the "high" than the "low" yeasts—Froberg, Neunkirchen, and Hofbrau exhibited the greatest power of attacking dextrin, but the actual proportion eliminated was difficult to ascertain owing to the inefficiency of the Fehling test for the determination of maltose. The ratio of non-maltose to maltose was greatest (3·3) with Froberg, and least (2·2) with Saaz yeast.

In ascertaining the amount of nitrogen consumed by each yeast, care was taken to prevent the precipitation of albuminoid matters by other agents during the fermentation. To this end the wort was acidified by 1 gm. of oxalic acid per litre, heated to nearly 100° C., and filtered, the free acid being then neutralised with lime. After a second filtration, and cold sterilisation, the wort was kept at 28° for 3 days and pitched. No precipitate was formed during fermentation, so that the weight of yeast and amount of nitrogen therein could be easily determined, the latter being estimated by the Kjeldahl-Aubin method. The results were as follows, the initial quantity of nitrogen in the wort being 0·610 grms. per litre:—

Yeast.	Weight of Yeast.	Nitrogen consumed.
	Grms. Per Litre.	Per Cent.
Brussels .....	2·60	33·7
Saaz .....	3·25	37·6
Bass .....	2·94	37·9
Froberg .....	3·11	32·8
Neunkirchen .....	2·81	28·1
48 .....	2·90	36·7
Hofbrau .....	2·51	32·9
Weihestephan .....	2·69	29·8
Meurant .....	2·97	26·0
Loewenbrau .....	2·62	36·8
Riga X .....	2·90	23·7
Maltose .....	2·13	17·1

from which it appears that as a rule, the "high" yeasts have the greater power of elimination; these figures are, however, only relative, and would appear proportionally smaller with increased percentages of nitrogen in the wort. An attempt was made to ascertain the nature of the nitrogenous matter consumed, and, though the method employed (that of Stutzer) is imperfect, the author concludes from the results that the albuminoids coagulable by cuprous hydroxide are but little, if at all, attacked by yeast, although the results might have been different in the absence of amide nitrogen.

From an experiment made with Hofbrau yeast, it would appear that in the first few days of fermentation the yeast absorbs nearly all the nitrogen it requires, the increase after the third day being only 0·36 per cent. during 10 days. After fermentation is over, the yeast yields up nitrogen to the wort—a fact which may explain the contradictory results obtained by Hyde and Wahl and Hantke. The decrease in the amount of dextrin was regular up to the 13th day, by which time one-third had disappeared.

The effect of aeration on nitrogen consumption was also studied, by the aid of low-fermentation Hofbrau and high-fermentation Brussels yeast in deep tubes and shallow vessels, the proportion removed being found greatest under the last-named conditions. This agrees with Briant's results, but the amount consumed by the yeast could not, in the flat vessels, be differentiated from that precipitated as a result of the exposure. In the deep wort a greater amount of dextrin was eliminated than in the shallow vessels, particularly with the low-fermentation yeasts. On the other hand, the "high" yeast attacked maltose least in the deep tubes, whereas the converse occurred with the "low" yeast.—C. S.

*Attenuation, Effect of Various Methods of Brewing on.*  
P. Petit. *La Bière*, 4, [12], 187-189.

EXPERIMENTS were made, with 100 kilos. of malt in each case, to ascertain whether any alteration in the attenuation could be brought about by modifying the method of brewing or fermentation, the same yeast being used throughout.

By the infusion method, with a steeping temperature of 51° C. for 30 minutes, heated to 74° for 20 minutes, agitated for 15 minutes, and left at rest for 30 minutes, the total maltose in the extract amounted to 68.9 per cent., and of this, one-third was formed during the first stage, 57 per cent. during the second, and 9 per cent. in the last two; this probably resulting from the solution of starchy matter in the grains, since complementary saccharification does not, according to the malto-dextrin theory, occur at this high temperature. A combination of the infusion and decoction methods gave a beer with an apparent attenuation of 72 per cent. (1 per cent. less than by the above method), but the yield was somewhat higher, being 61.5 (out of a theoretical yield of 70.5) per cent., against 60.2 per cent. by infusion alone.

With decoction methods it was found that whether two or three mashes were made, the resulting attenuation remained unaffected beyond a variation of 1 per cent., provided the same malt and yeast were employed in all cases. The maximum amount of sugar formed in the steeping stage was obtained at about 45° C., but the total amount at the end of the mashing process was approximately the same whatever the steeping temperature.

The only way in which the attenuation could be appreciably reduced was found to be by reserving 20 per cent. of the malt for addition in the final mash, which brought the total sugars down to 42.7 kilos. instead of 44 to 45 kilos., and produced a difference of from 5 to 7 per cent. in the attenuation. Similar results were obtained with 10 per cent. of rice, but the beer would not keep longer than 18 days. When rice is used in the final mash the saccharification should be tested by iodine to make sure of its completion, the conversion at this stage proceeding but slowly.—C. S.

*Cold Hop Storage.* L. Sterne. *J. Fed. Inst. Brewing*, 1896, 2, 537-541.

THE author refers to the observations of Braint and Meacham (this Journal, 1896, 731) on the subject; and, whilst generally endorsing them, states that in the opinion of American brewers the temperature of storage should be 32 to 34° F. instead of 38 to 40° F. A description is also given of the De la Vergne system of refrigeration.—J. L. B.

*Albuminoids, The Part played by, in Producing Lasting "Heads" in Beer.* W. Windisch. *Wochens. f. Brauerei*, 1896, 13, 1253-1254.

THE author infers from our present knowledge of the subject that two factors, *viz.*, carbonic acid and albuminoids, are together responsible for the production and retention of a "head" in beer. It is not only necessary that sufficient carbonic acid gas should be present, but also that a regular disengagement of gas should be going on in the liquid in order to enable it to retain this foam. The part played by albumose in this connection has been already indicated by the author (*Wochens. f. Brauerei*, 1893, 1358), albumose being a soluble, non-coagulable, peptonised albuminoid. Wulff's conclusion that peptones possess a "heading" influence is probably based on the fact that the commercial peptone used by him contained albumose, since this body is very commonly present therein. Römer has shown that albumoses are precipitated by zinc sulphate, whilst peptones are not; and by employing this method the author has separated from wort and beer, albuminoids possessed of marked foam-producing properties equal to those of albumose prepared by heating egg-albumin under pressure. During mashing, a conversion of both starch and albuminoids occurs, the latter of which form albumoses, amides, and perhaps peptones; the more advanced the growth of the malt, the more complete being the conversion, so that an undergrown malt contains more albumose than a fully grown one. Kussorow has also studied the influence of mashing upon the composition of wort, especially with

regard to albuminoids, and the behaviour of the wort towards yeast and beer "condition." The process of kilning also influences albuminoid conversion, the lengthy process of kilning adopted in England being recommended by the author. The reason why many excellent malts yield beers deficient in condition, and not retaining a "head," is to be sought in the excessive albuminoid conversion which takes place in the mash-tun, for such malts are rich in enzymes and readily convertible. To correct this fault a curtailing of the mashing process and approximation towards the English mashing temperatures of 158 to 163° F. are advised, for even at this temperature an abundance of albuminoid nourishment for the yeast is produced.—T. A. G.

*Alcoholic Fermentation, Retarding Influence of Various Reagents on.* T. Bokorny. *Allgem. Brauer u. Hopfen Zeit.* 1896, 36, 1573.

A *résumé* of investigations made by the author and other observers. Dilute sulphuric acid or potash (1 : 5,000) arrests fermentation completely. Copper sulphate (1 : 20,000) does not act as a complete preventative, whilst mercuric chloride has a slightly more pronounced effect. Certain oxidising bodies (KMnO<sub>4</sub>, Cl<sub>2</sub>, I<sub>2</sub>) are very destructive to yeast. Brouine, however, forms an exception, slight fermentation being observed in solutions containing 1 : 10,000. Potassium chlorate and iodate in 1 per cent. solution fail to arrest fermentation. Phosphorus (1 : 20,000) permits a slight fermentation to occur when the solution is incubated. A solution containing ortho-nitrocinnamic acid (0.1 per cent.) exhibits no fermentation when incubated for 24 hours. At 30° C.; under similar conditions the para-compound proved less effective. Ortho- and para-nitrotoluene (0.02 per cent.), ortho- and para-bromotoluene (0.1 per cent.), and ortho-toluidine sulphate (0.1 per cent.) arrest fermentation completely; whilst nitrobenzaldehyde (0.1 per cent.), potassium cyanide (0.02 per cent.), strychnine nitrate (0.02 per cent.), and quinine acetate (0.1 per cent.) fail to do so.—H. T. P.

*Alcohol derived from Cellulose and Wood.* Bull. de l'Assoc. des Chim. de Sucr. et de Dist. 1896, 14, 456.

SYSTEMATIC investigations upon the various conditions influencing saccharification, such as the nature and quantity of the acid, pressure, temperature, &c., have shown that if cellulose be treated with bisulphites, a maximum yield of 42 to 45 per cent. of sugar is obtained. 40 grms. of dry cellulose were heated for an hour and a half with 258 c.c. of 0.5 per cent. sulphuric acid, under a pressure of 6 to 8 atmospheres. When pine sawdust was used, the maximum yield of sugar (22.5 per cent.) resulted by heating for 15 minutes under the above-mentioned conditions. By longer heating the yield was reduced. Simultaneously with the production of sugar, an organic acid is formed which has not yet been investigated. After neutralisation the hydrolysed product was fermented.—J. L. B.

*Wines: Amount of Acetic Acid in Italian, Greek, and Spanish Red Wines.* H. Eckenroth. *Chem. Rundschau*, 1896, [6], 103-104.

DIFFERENT wines vary in their tendency to the formation of acetic acid, this frequently depending upon climatic conditions, cultivation, nature of the soil, &c.; but, generally speaking, red wines show a greater tendency to acidity than white wines, and the red wines of Italy, Greece, and Spain possess this property in a much higher degree than German and French wines. It is generally assumed that 0.2 gm. of acetic acid or more, per 100 c.c. will render a wine sharp and unpalatable. According to Nessler, ordinary white wines should not contain more than 0.07 gm. and red wines more than 0.1 gm. volatile acid (calculated as acetic) per 100 c.c. In judging a wine in this respect, it is not sufficient, however, to determine the amount of volatile acid, as no definite limit can be fixed as applicable in all cases: the wine must also be tested. An acid wine poor in alcohol will often be unpalatable if it contain 0.1 gm. of volatile acid in 100 c.c. whilst a sweet wine rich in alcohol and sugar may contain 0.2 gm. or more without any acidity being noticeable. There can also be no doubt that the taste of wines is considerably influenced by the

character of the volatile acids, and that much smaller quantities of butyric acid, than of acetic acid, will render wines unpalatable. The author has determined the total acidity, volatile acidity, and alcohol percentages in 24 samples of Italian, Greek, and Spanish red wines, and in almost all of these he found an exceptionally high percentage of volatile acids. Only 3 samples contained less than 0.2 grm. of acetic acid in 100 c.c., whilst in the others the percentages varied between 0.207 and 0.270. The total acidity varied between 0.743 and 0.895 and the alcohol between 12.05 and 14.81 per cent. by volume. All these samples were faultless wines and some of them of high quality, thus showing that 0.2 per cent. of volatile acid may in some cases be even considerably exceeded without injury to the wine.

—A. K. M.

*Wine, Effect of the too Frequent Sulphuring of Casks on.* W. Fresenius, Chem. Zeit. Rep. 20, [101], 302.

THE author gives a warning against the repeated sulphuring of casks, and using them for the storing of wine without further treatment; for though such casks prevent the formation of mildew, they are nevertheless unfitted for the storing of wine on account of the formation of considerable quantities of sulphuric acid.—I. S.

## PATENTS.

*Malt for Brewing, Impts. in the Treatment or Preparation of.* E. W. Walker, Leeds. Eng. Pat. 22,059, Nov. 20, 1895.

IN order to separate the perfectly malted grains of malt from the others, and stones, &c., the malt is mixed with water, when the first will float and may be skimmed off and dried.—A. L. S.

*Beer, New and Improved Process for Adding Iron to [as Lactate].* J. Kwiatkowski, Sereth, Bukowina, Austria. Eng. Pat. 21,118, Sept. 23, 1896.

THE inventor proposes to add lactate of iron to beer, in the proportion of 5–60 parts per 100,000.—A. L. S.

*Meters [Distillery] for Measuring Spirits and Distillates, Impts. in.* C. F. Chapp. Basse Terre, Guadalongre. Eng. Pat. 23,849, Dec. 12, 1895.

See under I., page 33.

*Specific Gravity, A New or Improved Apparatus for Separating Bodies of Different [such as Malt, Light and Heavy, in Water].* C. S. Meacham, Maidstone. Eng. Pat. 1177, Jan. 17, 1896.

See under XXIII., page 65.

*Filters, suitable for Wines, Spirits, or other Liquors: Impts. in.* R. Rendle, Pinner, Middlesex. Eng. Pat. 3911, Feb. 20, 1896.

THE filtering device consists of a shallow lenticular-shaped chamber, one side of which is composed of sheet metal and the other of finely-meshed metallic gauze, which, when in use, is kept uppermost. Any number of these chambers are fixed axially on a tube, which communicates with their interior and serves to carry off the filtered liquid. The filtering material is composed of finely-divided asbestos, which is mixed with the first portion of the liquid to be

filtered; the tube and filtering chambers being immersed in this liquid and suction applied to the tube, or pressure to the liquid, the finely-divided asbestos is deposited on the surface of the gauze, and the liquid to be filtered soon passes through bright.—A. L. S.

*Seasoning Casks, Intended to Contain Wine, Spirits, and other Delicate Liquids, Ale, Stout, and the like: Impts. in.* F. Ivison. Jerez de la Frontera, Spain. Eng. Pat. 11,162, June 26, 1896.

A SMALL quantity of liquid ammonia is poured into the cask to be seasoned, which is then filled with steam at about 15 lb. pressure, and allowed to stand one hour and a half. The cask is then washed, when it will be found to be perfectly seasoned. For a 14 gallon cask, about one pint of ammonia of a sp. gr. 0.94 will be required, and a proportionate quantity for other casks of different surface area. American oak requires longer treatment and more ammonia.—A. L. S.

## XXIII.—FOODS; SANITATION, WATER PURIFICATION, & DISINFECTANTS.

### (A.)—FOODS.

*Wheaten Flour, the Suitability of, for Bread Making; A Chemical Method for Determining.* E. Fleurent. Comptes. rend. 1896, 123, [19], 753–758.

THE comparative suitability of different flours for bread making, is essentially determined by the physical properties (in respect to elasticity, &c.) of the gluten respectively contained in them. The author shows that such differences in properties are clearly marked by corresponding variations in the relative proportions of glutenin and gliadin present in the crude gluten, and bases on this discovery the following method of examination. The gluten, obtained in the usual way (by kneading and washing in a current of water) from 33.33 grms. of flour, is divided into small pieces, and mixed in a wide-mouthed stoppered bottle with a quantity of glass beads, and 80 c.c. of alcoholic potash of known strength (3 grms. of KOH per litre of 70 per cent. alcohol). The mixture is well shaken at intervals until complete solution is effected (36–48 hours). A current of CO<sub>2</sub> is then passed to saturation through the liquid, and the latter transferred to a graduated flask, diluted to 110 c.c. with water and briskly mixed; 20 c.c. are then withdrawn before the precipitate has time to settle, evaporated in a tared dish, and dried to constant weight. The weight of residue, minus the quantity of K<sub>2</sub>CO<sub>3</sub> contained in 20 c.c. of the liquid, represents *total gluten*. Another portion of the liquid is filtered to separate the insoluble glutenin, and 20 c.c. of the clear filtrate evaporated, &c. as above. The *gliadin* (with traces of conglutin) is thus found. The difference between this and the previous result represents *glutenin*. In case of flours containing 9 per cent. or more of gluten, it is advisable to use 150 c.c. of alcoholic potash for solution and to make up to 200 c.c.

A series of flours, previously examined as above, were submitted to careful practical tests, the results of which lead to the following conclusions:—

1. Leaving out of consideration the percentage of total gluten, the best results are obtained with flour, the gluten of which approaches most closely to the centesimal composition, glutenin, 25 per cent.; gliadin, 75 per cent.; (ratio, one-third).

2. Flour, in which the ratio of glutenin to gliadin is one-fourth, develops well during fermentation; but the dough again collapses and becomes compact during baking.

With such flour, the proportion of water normally employed must be reduced.

3. When the ratio of glutenin to gliadin rises to one-half, the flour becomes almost unworkable; the dough does not develop either during fermentation or baking, and the bread remains solid and indigestible.

4. A comparison between bread baked from flour, conforming to the standard laid down under (1), and that produced from flour varying 2 per cent. either way from the typical values, reveals differences that are readily perceived by an expert.—H. T. P.

*Bread-Making. Mineral Oil used in. Brotol.* L. Hane-mann. Chem. Zeit. 1896, 20, 1023.

THE sides of loaves which are to be packed in the ovens so closely that they are in contact, have to be smeared with grease before introducing into the oven. If this smearing is omitted, the loaves cake together into one mass on baking. Generally they are smeared with lard or butter, but a few years ago, "Brotol" (bread oil) was introduced by a Hamburg firm as a cheap substitute. It was effective for the baker's purpose, but being a mineral oil it was in other respects quite unsuitable. One baker, when preparing a meal, used it in the place of butter, and illness of the whole family resulted. The Supreme Imperial Court has recently made the smearing of bread with this oil a penal offence in case of resulting injury to health. A warning to bakers not to use the oil has been issued in Bremen.

—J. A. E.

*Army Bread. Note upon a New.* Balkand. Comptes. rend. 123, 1007—1009.

THE new army bread which is being substituted for the old army biscuit is made from a fine flour "bolted" (sifted) at 30/100, water, salt, and fresh yeast. The biscuit contained only flour, "bolted" at 20/100, and water. The author gives details of the size of the new bread rolls, and of their characteristics as regards crumb and crust. He has analysed three samples of the new bread, one of the old army biscuit, and also four other samples of breads made in France. The results of these eight analyses are given; and an examination of the figures, in conjunction with the results of some earlier study of his own on flours, demonstrates, he considers, the following points:—

1. The constituents of a pure wheat-flour bread, in its dry state, agree with those of the flour from which it is made. The nitrogen, cellulose, and phosphates are in the same proportion. The ash is increased owing to the salt. The fat constituents, more or less modified by the treatment undergone in baking or in the analysis, are reduced.

2. The nitrogenous matter and the phosphates which are least in the well-bolted (sifted) flours, are naturally in less proportion in bread made with flour bolted at 40/100 than in bread made with flour "bolted" at 20/100. The latter bread is consequently the more nutritious.

3. The new army bread, made with a better bolted flour than the old army biscuit, contains less nitrogenous matter. On this account the campaign rations of fresh meat have been raised from 300 to 500 grms., and the soldier does not lose by the change in the flour.

4. The change to cylinder rolls in milling has caused a complete disappearance of brown bread in the towns; and this displacement of brown bread by white is spreading rapidly over the country districts. Whereas 30 years ago, 83 kilos. of bread-flour were generally obtained per 100 kilos. of wheat; to-day only 71—72 kilos. are recovered from the same amount on farms in the country districts of Bresse; and this return is probably correct for other country districts. This loss of nitrogenous matter and phosphates has not been balanced by any increase in meat or other nitrogenous food-stuff for the greater number of consumers. Many doctors, including Prof. Tarnier, believe the lessening vitality of the race in the richest towns and departments of France, is due to such a cause, and it would seem desirable to prevent this excessive bolting (sifting) of flour intended for nourishment.—J. B. C. K.

## PATENTS.

*The Preservation [with Iodine and Iodides] of Meat, Fish, and other Animal Substances, and the Manufacture of Food Stuffs therefrom, An Improved Process for.* L. P. J. Revel and J. M. Campagne, Paris, France. Eng. Pat. 22,989, Nov. 30, 1895.

THE meat (raw or cooked), or fish, eggs, &c. is steeped for 15 minutes in a bath composed of water, 1,000 grms.; potassium iodide, 15 grms.; iodine, 5 grms. (or tincture of iodine, 20 grms.), and allowed to dry. Meat, fish, &c. thus treated, will retain their original freshness for 4—5 days, and then commence to slowly dry (without becoming in the least putrid), and in this dried condition may be preserved almost indefinitely. Instead of steeping in the bath, animal substances may be brushed over with or wrapped in cloth saturated with the preservative solution. Another claim relates to the production of "iodized meat bread," made by incorporating about 3 per cent. of ground, dried, iodized meat with the dough.—H. T. P.

*Effervescent Beverages, Impts. in the Manufacture of, in the Preparation of the Materials Used in the said Manufacture, and in Obtaining Useful Products therefrom. [Bisulphate and Bicarbonate of Soda.]* J. Hargreaves, Farnworth-in-Widnes. Eng. Pat. 925, Jan. 14, 1896.

BISULPHATE of soda or other acid sulphate of soda is used in combination with bicarbonate of soda for the production of carbonic anhydride in gasogenes or similar apparatus. The bisulphate is prepared by fusing and casting it into spheres, rods, or plates with a known and defined content of free acid. It is packed into parcels or portions together with such a proportion of bicarbonate of soda as will neutralise its content of free acid. After the evolution of the carbonic anhydride, the mother liquor is crystallised to form Glaubers salts or concentrated to form anhydrous or other desired sulphate. To obtain the largest production of sulphate of soda, the mother liquor from one charge is added to the above-mentioned mixture, which is used for succeeding charges.—D. B.

*Sterilising Apparatus [for Milk, &c.], Impts. in.* S. S. Bromhead, London. From F. Dierks and J. Möllmann, Osnabrück, Germany. Eng. Pat. 3572, Feb. 17, 1896.

AN apparatus so arranged that the bottles, &c., containing the material undergoing sterilisation, may be automatically closed prior to their removal from the heating chamber. To this end the latter is traversed by one or more excentric shafts from which the bottles are suspended by their stoppers (some form of lever stopper), a rigid connection being secured by means of square pins projecting from the shaft, and corresponding "eyes" fitted to the stoppers. A half-turn imparted to the shaft from the outside of the chamber then snatches to close (or open) the bottles when required.—H. T. P.

*Sterilising or Pasteurising Milk and Cream, An improved Process of.* L. G. Fagersten and C. F. P. Kerssell, Chicago, U.S.A. Eng. Pat. 18,275, Aug. 18, 1896.

THE improvement consists in adding to the milk, prior to sterilisation, sufficient wax or solid paraffin, &c. to form, when melted, a continuous layer on the surface of the

liquid. The solid crust of wax left on cooling, will, it is claimed, prevent that separation of milk-fat, to which sterilised milk is ordinarily somewhat liable.—H. T. P.

See under L., page 31.

### (B.)—SANITATION; WATER PURIFICATION.

*Sewage, The Ultimate Purification of.* G. Thudichum.

A paper read before the Society of Engineers, Dec. 7, 1896.

THE author's object was to describe, for the benefit of engineers and others, the biological purification of sewage by filtration, and to contrast this method with purification by land irrigation.

Mr. Dibdin had shown that any process adopted for the purification of sewage must be subordinated to the requirements of the micro-organisms. Sterilisation was a mistake, since as soon as antiseptic action was neutralised by dilution, putrefaction was set up. Direct oxidation by air could not be induced in the absence of microbes. An attempt to effect oxidation without putrefaction by adding organisms to the sewage, failed, and the general experience of the author goes to prove that all sewage effluents produced by chemical precipitation are finally purified only by a putrefactive process. The discovery of these facts naturally led to the attempt to effect purification by adding the sewage to the organisms previously established in a filter bed, under the necessary conditions. The Massachusetts experiments showed that, in this way, 97 per cent. of the organic matter contained in raw sewage could be removed, but not more than 60,000 gallons of sewage per acre per diem could be re-treated. Mr. Dibdin had gone further, and had succeeded, by experiments conducted upon London sewage, in purifying 1,000,000 galls. of sewage effluent per acre per diem, the oxidisable organic matter being reduced on an average by 80 per cent. (See this Journal, 14, 1895, 915—922). The depth of Mr. Dibdin's filter must not be taken as a necessary factor in its efficiency; cubic contents and not surface area should be considered, as the work is all done in the body of the filter. The depth is probably limited only by the necessity for free air supply.

The conditions unfavourable to the success of irrigation farms were then pointed out, the principal objection being the necessity for applying sewage to the land irrespective of the condition of the latter or of the requirements of the crops. Also nuisance, more or less pronounced, is almost always caused. It is suggested that where sewage farms already exist, the filter system should be adopted, and the filtrate, which contains nitrates and other fertilising ingredients, should be applied to the land when likely to prove beneficial, and should at other times be allowed to escape directly into a watercourse.

The attitude of the Local Government Board in insisting upon irrigation, was criticised and condemned, and mention was made of various places—Wolverhampton, Sutton, Aylesbury, Exeter—where the method of filtration adopted in the Barking experiments has been successfully followed.

—L. A.

*Flood-Water of the Seine, the Yonne, and the Marne: Nitric Acid in.* T. Schloesing. Comptes rend. 123, 919—923.

THE author refers to a test made by Boussingault in March 1876, when the flood-water of the Seine at Paris contained 1.2 mgrm. nitric acid per litre, and he compares this with his own tests, made in November 1896, of the flood-waters of the Seine, the Yonne, and the Marne. These varied from 3.13 up to 5.08 mgrms. of nitric acid per litre.—J. B. C. K.

*Phosphorus, The Toxic Action of Aqueous Solutions, and the Solubility in Water of.* Th. Bokorny. Chem. Zeit. 1896, 20, 1022.

THE author prepared aqueous solutions of phosphorus by adding alcohol to solution of phosphorus in carbon bisul-

phide, and pouring the mixture into a large volume of boiling water.

As a result of the experiments, phosphorus cannot be regarded as a very powerful poison towards the lower organisms. Water in which phosphorus had for some time been kept was much more rapidly fatal to them than the aqueous solution prepared as above. The powerful toxic properties of this water appear to be due to the ozone, hydrogen peroxide, and phosphorous acid which the phosphorus produces rather than to the phosphorus itself. To the higher animals and man, phosphorus is a virulent poison; but the author is not aware that the action of aqueous solutions on vertebrates has yet been studied.

—J. A. B.

*Nitroglycerin, Researches on the Toxic Power of.*

Th. Bokorny. Chem. Zeit. 1896, 20, 1021.

AQUEOUS solutions of 0.1 per cent. of mineral salts (calcium nitrate, magnesium sulphate, and mono-potassium phosphate) were prepared, containing the requisite quantity of 30 per cent. solution of nitroglycerin in absolute alcohol to give them percentages of 0.2, 0.1, 0.05, and 0.01 of nitroglycerin. The vitality of lower organisms in each of these four solutions was observed, and it was found to be impaired only in that containing 0.2 per cent. of nitroglycerin. In 24 hours the diatoms, infusoria, and amebae therein ceased motion; but even after three days many filaments of spirogyra remained distended, though the nuclei and chlorophyll bands were displaced. On adding 10 per cent. of cane sugar, some ammonium sulphate and a trace of brewers' yeast to the solutions, the yeast propagated itself freely. Some of the organisms at least had assimilated nitroglycerin, as it could not afterwards be detected in the solutions used. Therefore, it appears to be only poisonous to a small extent to the lower animals and plants, though powerfully toxic in the case of the higher animals and man. Its action on animals is considered by Cagnoli to be due to formation of nitrous acid, and, since the latter is poisonous to plants also, it is argued that the lower organisms can assimilate nitroglycerin without formation of nitrous acid.

Nitro-ethane is also a powerful poison towards the higher animals. A series of experiments similar to those made on nitroglycerin showed that it is quite harmless in the case of lower organisms.—J. A. B.

*Lead in Water, A Simple Method of Detecting and Estimating Minute Quantities of.* J. C. Berntrup. Chem. Zeit. 1896, 20, 1020.

See under XXIII., page 66.

### PATENTS.

*Sewage, Treatment of, at Precipitating and at Outfall Works [Liming, followed by Manganate of Soda Treatment]; Improved Means and Appliances for.* R. H. Reeves, London. Eng. Pat. 22,502, Nov. 25, 1895.

LIME-WATER is prepared by the action of high-pressure jets of water on unslaked lime (and other chemical solutions similarly). This is caused to commingle with the sewage whilst in a state of agitation. After settling, the supernatant liquid is run off, and treated with, preferably, manganate of soda and sulphuric acid; it is then filtered through artificial filter-beds. The sludge is not filter-pressed, but is dried in a thick state, as peat is; the manurial value is thus said to be greater.—L. A.

*Sewage and other Liquids, Filtering [Combined Filtration and Aeration]; Impts. in or connected with Apparatus for.* T. B. Jones, Harrogate. Eng. Pat. 24,943, Dec. 30, 1895.

THE filtering material is contained in a series of trays supported one above another, with intervening air-spaces, by a vertical open framework. The bottoms of the trays are perforated, and the filtering material in each is covered by a loose perforated plate. The liquid falls in a thin stream on to the perforated plate of the topmost tray, and descends through the entire series. The trays are made to slide in and out on rollers.—L. A.

*Destructor Furnaces for the Treatment of Town Refuse, Impts. in or connected with.* S. Willoughby, Chiswick, Middlesex. Eng. Pat. 2901, Feb. 8, 1896.

The general principles of the destructor, which formed the subject of a previous specification (Eng. Pat. 20,719, 1894), are shown in the illustration.

Fig. 1.

DESTRUCTOR FURNACE.

The refuse matter is fed into the hopper C, and falls into the inclined rotating flue or combustion chamber B, in travelling along which it is consumed by the flame and hot air from the furnace A, and the ashes fall into the truck J. The improvements now described consist chiefly of arrangements for the admission of an auxiliary supply of air to burn the refuse more completely. The anterior end of the combustion chamber is enlarged and provided with passages, B<sup>1</sup>, through which air may be drawn by the chimney draught, or forced under pressure; or passages, A', may be provided, through the crown or walls of the furnace, so as to heat the air before it meets the refuse.

—L. A.

anf Actien vormalis E. Schering, Berlin. Eng. Pat. 22,625, Nov. 26, 1895.

PARCHMENT paper is drawn through a 2 to 3 per cent. solution of pyroxylin in ether-alcohol or other solvent. The film left by evaporation is firmly united to such paper, whereas from ordinary paper, water detaches it easily. If the parchment paper be first treated with a 3 to 5 per cent. solution of cuprammonium, a successful result is certain, even if the paper be very stout and hard.—L. A.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

### XIX.—PAPER, PASTEBOARD, Etc.

*Indian Hemp [Refuse Plant Fibre].* H. C. Dyer. Indian Pharmacist, 1896, 1, 85.

THERE is no reason why the refuse from the plants cultivated for the sake of the drug should not be utilised. The refuse plants are well fitted for the manufacture of paper.

The term "hemp" is employed for the fibres from several distinct plants. Thus, New Zealand hemp is obtained from *Phormium tenax*, sisal hemp from a variety of aloe, sun hemp from *Crotalaria*, Manila hemp from *Musa textilis*, &c. The best—hemp proper—from *Cannabis sativa*, is produced in Italy.

In cultivating hemp for its fibre, a rich soil is essential. The plant thrives particularly well in moist alluvial situations, in a fine soil rich in vegetable matter. The carefully selected seed is sown rather thickly—in India generally broadcast, in Europe in drills. The ground is usually tilled earlier, and well pulverised and levelled. The plant is dioecious. The male plants flower first, and are cropped off close to the ground; the female plants are left till they produce seed, and are then cropped. The stems are handled one by one, and the leaves cut off. They are then tied in bundles and steeped in water. The retting process is also effected by exposure to dew, chemicals, or snow. When the soft tissues have more or less disappeared, the bundles are unloosed and the stems spread out to dry, and when dry the fibre is stripped by hand. The coarse fibre so obtained is finally cleaned by scutching.

To preserve the quality of the fibre, change of seed must be made every season. India exports hemp fibre to the value of 45,900 rupees, while the imports amount to over 10 lakhs of rupees worth annually.—A. C. W.

### PATENT.

*Paper which is Proof against the Action of Water, Air, Grease, and Weak Acids; Impts. in the Manufacture of.* A. Zimmermann, London. From The Chemische Fabrik

*Angelica Oil.* G. Ciamician and P. Silber. Ber. 29, 1811.

IN the lower fractions of the oil of *Angelica archangelica* previous investigators observed one of the valeric acids and oxymyristic acid, also a terpene boiling at 172° C., but the contents of the higher fractions were never investigated. This oil was found by the authors to consist chiefly of a high boiling terpene and an oxy-acid C<sub>15</sub>H<sub>30</sub>O<sub>3</sub>. The latter, however, is not present in the free state, but is formed on saponifying the oil with alcoholic potash. Amongst the products of this saponification a valeric acid, which was subsequently identified with methyl-ethyl acetic acid, was also observed.—C. O. W.

*o- and p-Nitrophenol and their Technical Uses.* [Preparing Phenacetin.] L. Paul. Zeits. f. ang. Chem. 1896, 587—595.

PHENOL, on nitration, gives two mono-nitro derivatives, which, as is known, are separated by distilling with steam. The *o*-nitro compound passes over with the steam, and is thus obtained in a condition sufficiently pure for conversion into *o*-nitranisol without further preparation. The *p*-nitro compound which remains behind in the retort along with tarry matters is isolated by repeated crystallisation from xylene. It serves as the intermediate material for the manufacture of *p*-nitrophenetol, phenacetin, and *p*-amido-phenol.

As the latter compounds are of less industrial importance than the compounds derived from *o*-nitrophenol, a method for preparing the latter from phenol without forming the *p*-isomeride, is desired. A method devised with this object by The Farbenfabriken vormals F. Bayer and Co. (Ger. Pat. 43,515), consists in converting phenol into its *p*-sulphonic acid, nitrating this to obtain the *o*-nitro derivative, and then hydrolysing to remove the sulpho group. It, however, gives an unsatisfactory yield.

*o-Nitranisol.*—A hot solution of 50 grms. of *o*-nitrophenol and 15 grms. of caustic soda in 100 c.c. of water, is placed with 300 c.c. of methylic alcohol and 10 grms. of

sodium carbonate in a digester, attached to a methyl chloride cylinder.

The taps (b) and (c) are kept closed, while the tap connected with the cylinder is opened for a few minutes, then this tap having been closed taps (b) and (c) are successively opened. After a while, (b) is opened and finally the tap connected with the cylinder. The pressure inside the digester rises to 3—4 atmos. and the reaction is allowed to continue for half-an-hour. The taps are thereupon closed, and the digester is heated gradually to 100°, the pressure increasing to 6—7 atmos. After heating for about 15 hours, the contents of the digester are freed from alcohol by distillation and the lower oily layer of *o*-nitranisol is separated from the aqueous solution. To purify the product, it is extracted with ether, or is distilled. The yield (45 grms.) is about 83 per cent. of the theoretical.

**Dianisidine.**—100 grms. of *o*-nitranisol, 200 grms. of methylic alcohol and 60—70 grms. of caustic soda solution at 35°—40° B. are heated together to 70° in a cast-iron digester, furnished with an agitator. 150 grms. of zinc dust in portions of 5—10 grms. are added, the temperature being allowed to fall to 50°—55°, and being maintained thereat until the reaction is completed. 200 c.c. of hot water are next added and the mixture is distilled until the alcohol and about 25 c.c. of a milky liquid (containing the anisidine formed) have passed over. The residue is placed in a large dish and washed first with 425—450 c.c. of concentrated hydrochloric acid diluted with 2 litres of water and cooled to below 10°, and then several times with water. It is next treated with hydrochloric acid (about 100 c.c. of concentrated acid, and 1000 c.c. of water) below 10°, any lumps of hydrazo-anisol present being crushed to bring them into action. The mixture is then filtered and the dianisidine precipitated as sulphate by the addition of sodium sulphate. The yields obtained in two experiments amounted to 41 and 44 grms. respectively.

***p*-Phenolsulphonic Acid.**—25 kilos. of phenol are mixed with 28 kilos. of concentrated sulphuric acid, and heated at 90°—100° for 24 hours. The solution is poured into 150 kilos. of a solution of common salt, the precipitated sodium phenol-*p*-sulphonate being collected on a woollen filter, pressed, and dried; it amounts to 76 kilos. It is purified by re-crystallising from 30 litres of water.

***o*-Nitrophenol-*p*-Sulphonic Acid.**—31 kilos. of sodium phenol-*p*-sulphonate, purified as described, are dissolved together with 31 kilos. of sodium nitrate in 150 litres of water at 40°. 31 kilos. of concentrated sulphuric acid are added in a fine stream, its addition producing a rise of temperature. When this reaches 65°—70°, the reaction commences. After it is over and the solution has cooled, the aqueous solution is withdrawn from the mass of crystals which deposits, the latter being pressed, dissolved in boiling water, and again crystallised, or, to save time, the acid is converted into its readily crystallisable sodium salt, which is accomplished by adding common salt to the solution.

***o*-Nitromethoxybenzene-*p*-sulphonic Acid.**—A mixture of 100 grms. of sodium *o*-nitrophenol-*p*-sulphonate, 25 grms. of sodium carbonate, 300 c.c. of water, and 66 grms. of methyl iodide, is heated in an autoclave at 100°—110° until the pressure, which at first is considerable, has decreased. The sodium salt of the methoxy-compound which is produced is purified by crystallisation.

**Anisidine- and Phenetidine-sulphonic Acids.**—100 grms. of *o*-nitrophenol-*p*-sulphonic acid are added to a solution of 400 grms. of stannous chloride in 400 grms. of hydrochloric acid at 20° B., at a temperature of about 60°. The mixture is diluted with water and the tin precipitated by

means of sodium sulphide, after which the solution is filtered and evaporated. Common salt first separates, and then sodium phenetidine-sulphonate.

**Methoxy- and Ethoxyazobenzene-disulphonic Acids.**—250 grms. of sodium *o*-nitrophenol-*p*-sulphonate, 750 c.c. of water, and 500 c.c. of caustic soda solution at 10° B., are heated together to 70°, and, while the temperature is maintained at 70°—80°, 100—150 grms. of zinc dust are gradually added. The mass is mixed with 2 litres of common salt solution, the residue filter-pressed, dissolved in 1½ litre of hot water, filtered, and the sodium salt precipitated by the addition of 250—260 grms. of common salt. 192 grms. of it, or 90 per cent., of the quantity theoretically producible, are obtained.

**Dianisidine- and Diphenetidine-disulphonic Acids.**—For the preparation of diphenetidine-disulphonic acid, 47 grms. of sodium ethoxyazobenzene-disulphonate are dissolved in 300—400 c.c. of water, and are treated, at a temperature not exceeding 10°, with a solution of 23.5 grms. of stannous chloride in 45 grms. of hydrochloric acid at 12° B., 50 c.c. of a 16-per cent. solution of the same salt being added when the solution has become colourless. The tin is next precipitated with sodium sulphide, and then the diphenetidine-disulphonic acid with sodium sulphate. The latter is washed with sodium sulphate solution and pressed, 113 grms. of a paste containing 43 grms. of diphenetidine-disulphonic acid being obtained.

***o*-Amidophenol.**—3 kilos. of *o*-nitrophenol are ground with 750 c.c. of water and 2 litres of concentrated ammonia. The pasty mass of the ammonium salt thus obtained is placed in a suitable vessel with 6 litres of water, and heated to 20°. The reduction is effected with hydrogen sulphide, which is passed into the solution while it is slowly heated to 40°. When the conversion of the nitro-compound is complete, the current of gas is stopped. The solution is allowed to stand for two days and is then filtered. The residue, after being made into a paste with water, and filter-pressed, is dissolved in hot water and crystallised. 1.5 kilos. of the amido-compound are obtained, for the production of which 15 kilos. of ferrous sulphide and 65 kilos. of hydrochloric acid at 12° B. are consumed in generating the hydrogen sulphide required.

***p*-Amidophenol.**—25 kilos. of *p*-nitrophenol are added to 180 kilos. of hydrochloric acid at 20° B. and 75 kilos. of tin, contained in an earthenware vessel, the temperature rising to 100°—106°. 200 kilos. of concentrated sulphuric acid are next added in a fine stream. After standing for three days, the *p*-amidophenol sulphate which has separated, is filtered off, drained, dissolved in 200 litres of cold water, and decomposed with soda, 1 kilo. of sodium bisulphite being added to the solution to protect the precipitated base from oxidation. The precipitate is filter-pressed and dissolved in 200—300 litres of boiling water, along with 10 kilos. of sodium bisulphite, the filtered solution on cooling, depositing the base in colourless needles.

***p*-Nitrophenetol.**—For the preparation of this, the *p*-nitrophenol used is first purified by a method such as the following:—806 grms. of crude *p*-nitrophenol are dissolved in 8—10 litres of hot water, 250 grms. of chalk added, the solution filtered, treated with 200 grms. of soda and 5 kilos. of common salt, again filtered, and set aside to crystallise. 950 grms. of the purified sodium compound were thus obtained in one experiment.

The ethylation is effected by heating together under a reflux condenser for 10 hours, a mixture of 480 grms. of the salt purified as above described, 3,120 grms. of methylic alcohol, 300 grms. of ethyl bromide, and 100 grms. of sodium carbonate. After cooling, the separated *p*-nitrophenetol is filtered off, washed with hot water until the wash-water has only a pale brown colour, and crystallised from alcohol. 340 grms. of it are obtained.

***p*-Amidophenetol.**—212 grms. of *p*-nitrophenetol are gradually added to a solution of 848 grms. of stannous chloride in 1,060 grms. of hydrochloric acid at 50°—60°. The amido-compound formed is precipitated from the solution as hydrochloride by the addition of concentrated hydrochloric acid. It is filtered off, drained, and freed from tin by dissolving it in hot water, acidulated with hydrochloric acid, and placing a few strips of sheet zinc in the

solution. Long, colourless prisms of the hydrochloride are obtained, in amount corresponding with 60 per cent. of the theoretical yield.

*Phenacetin*.—16.7 grms. of *p*-amidophenol hydrochloride, 8.7 grms. of anhydrous sodium acetate, and 83 grms. of acetic acid, are heated under a reflux condenser for 3 hours. The mixture is poured into 10 times its volume of boiling water and the solution filtered. On cooling, the phenacetin produced, deposits in pale red crystals. It is purified by repeated filtration of its solution through animal charcoal and crystallisation, being ultimately obtained in minute, lustrous crystals. The yield obtainable is 90 per cent. of the theoretical.—E. B.

*Apiol, On a New*. G. Ciamician and P. Silber.  
Ber. 29, 1799.

THE higher boiling fraction of a dill oil, obtained from Indian seed, was found to consist chiefly of a new apiol, boiling at 285° C. This new apiol contains two methoxyl groups, but differs from ordinary apiol in that it is an almost odourless, oily, and non-crystallisable liquid, insoluble in water, but readily soluble in all other ordinary solvents. Its behaviour towards caustic soda and sulphuric acid is the same as that of ordinary apiol. On treatment with alcoholic potash or sodium ethylate, the new apiol forms a beautifully crystallised isapiol, melting at 41° C. This isapiol from dill oil is identical with ordinary apiol. Like ordinary apiol the new isapiol on oxidation, yielded the same tetramethylapionol—

The new apiol produces a dimethyl apionol, which is isomeric with that obtained from ordinary apiol, its diacetyl derivative melting at 85° C., whilst that of the latter melts at 144° C. The dimethylapionol obtained from the new apiol, on methylation yields however, a tetramethylapionol identical with that obtained by the same treatment of the dimethylapionol derived from ordinary apiol. From this it follows that ordinary apiol and the new one, are derivatives of the same tetravalent phenol.—C. O. W.

*Rose Water, An Acid contained in*. E. Charabot and G. Chiris. Comptes rend. 1896, 123, [19], 752—753.

THE authors have observed that rose water always contains a trace of an organic acid, and consider it to be produced during distillation (i.e., of roses with water) by the partial saponification of the levo-xyratory ether, which Dupont and Guerlain (Comptes rend. 123, 700) have shown to be present in oil of roses. The softer odour and higher rotatory power of French, as compared with Turkish rose oil, are ascribed to the more perfect method of distillation employed for the preparation of the former essence, whereby the destruction of the ethereal substance is reduced to a minimum.—H. T. P.

*Quinine, Sulphate, The Efflorescent Nature of Crystallised*. A. J. Cownley. Pharm. J. 1896, 57, 525.

THE author, some years back, published a paper (Pharm. J. 3, 7, 189) drawing attention to the peculiar efflorescent character of crystalline quinine sulphate, and he now again sets forth the facts then established.

1. Crystallised quinine sulphate, containing 7½ mols. of water of crystallisation, when freely exposed to air at the ordinary temperature, rapidly effloresces until it attains the composition of a sulphate containing 2 mols. of water.

2. Freshly-crystallised quinine sulphate approximates to 7½ mols. of water of crystallisation.

3. Crystalline quinine sulphate is rendered anhydrous at 100° C.

4. The anhydrous salt, when freely exposed to air at the ordinary temperature, rapidly absorbs water until it has the composition of a sulphate with 2 mols. of water, but when access of air is retarded, the water of crystallisation in the salt is of a varying quantity, and bears no constant relation to the salt until 2 mols. of water have been absorbed.

The author, in view of these results, advocates that the official quinine sulphate should be the air-dried salt, having the following composition:—

The variation in the amount of water in commercial samples of quinine sulphate is shown by the fact that in 40 samples examined, the amount ranged from 8.1 to 15.95 per cent. (Pharm. J. [3], 16, 797).—A. S.

## PATENTS.

*New Medicinal Compounds [Anti-Rheumatic Agent]. Manufacture or Preparation and Production of*. J. Y. Johnson, London. From The Vereinigte Chininfabriken Zimmer and Co., Frankfurt-on-the-Maine. Eng. Pat. 1202, January 17, 1896.

THIS patent claims as new bodies, alkyl derivatives of the compound of *p*-amidophenol with *m*-hydroxyvalerylaldehyde,  $\text{RO} \cdot \text{C}_6\text{H}_4\text{N} : \text{CH} \cdot \text{C}_6\text{H}_3(\text{OH})(\text{OR})$ , ( $\text{R} = \text{CH}_3$  or  $\text{C}_2\text{H}_5$ ), and the process of manufacture, which consists in condensing the two substances mentioned and alkylating the product, or in condensing the previously alkylated substances, or alkylating one of them, then condensing, and finally alkylating the second hydroxyl group.—A. C. W.

*Aromatic Waters, such as Elder Flower Water, Rose Water, and the like [Combined Action of Acid and Fermentation]*; Impt. in the Manufacture of. P. Auehachie, London. Eng. Pat. 19,603, Sept. 4, 1896.

THE addition of tartaric, citric, or other non-volatile organic or inorganic acid to the aromatic herbs or flowers, and after heating to boiling, allowing to stand for two or three days, or until fermentation begins, is claimed. The distilled product is of purer quality and odour.—A. C. W.

*Saccharine, Impts. in the Manufacture of*. [Action of Ammonia on *o*-Benzoyl Sulphonic Dichloride.] Chemische Fabrik von Heyden, Radebeul, Germany. Eng. Pat. 21,026, Sept. 22, 1896.

THE process claimed in Eng. Pat. 1885, 6626, for preparing the ammonium salt of saccharine by treating *o*-benzoyl-sulphonic chloride with ammonium carbonate gives a very small yield. The present patent claims the process which consists in converting the dichloride into the diamide by adding it to a cooled aqueous solution of ammonia or ammonium carbonate in excess with constant stirring, finally heating to 100° C., and then boiling the diamide with a dilute alkali (1 molecule) to convert it into a saccharine salt.

—A. C. W.

## XXI.—PHOTOGRAPHY.

### PATENTS.

*Coloured Plates for Obtaining Coloured Representations by Photography, Impts. relating to*. A. Baumgartner, Lorrach, Germany. Eng. Pat. 22,138, Nov. 20, 1895.

ONE, or more, oil colour is printed on to a celluloid plate, previously coated with gelatin, from a granulated lithographic stone or zinc plate. The plate is then dipped into

an aniline dye, which will dye those parts only which are not covered by the oil paint, after which process another oil colour may be printed on, partly on the dyed, and partly on the printed spots, whereby compound shades may be produced.—I. S.

*Photographic Developers [Quinoline Hydride Derivatives], Impts. in.* A. M. Clark, London. From Lembach and Schleicher, Riehrich-on-the-Rhine. Eng. Pat. 371, Jan. 6, 1896.

THE use of the hydrides of hydroxyquinoline and hydroxytoluquinoline and their substitution products as photographic developers is claimed, and as a new developer, a solution of tetrahydro-o-hydroxyquinoline or other of the above compounds in alkaline sodium sulphite solution. The concentrated solution is diluted before use. Fogginess due to overdeveloping has not been observed in the use of these compounds.—A. C. W.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*Cap Composition, The Analysis of.* F. W. Jones and F. A. Wilcox. Chem. News, 1896, 74, 283.

See under XXIII., page 67.

### PATENTS.

*Smokeless Explosives, Impts. in the Manufacture of.* H. Maxim, London. Eng. Pat. 14,311, Aug. 30, 1895.

IN making explosives consisting of nitrocellulose and nitroglycerin gelatinised by means of acetone, the inventor proposes to add to the highly nitrated guncotton, 8—10 per cent. of nitrocellulose soluble in nitroglycerin, and then treat the mixture of these nitrocelluloses and nitroglycerin with acetone in a closed vessel which can be heated.

The addition of the nitrocellulose soluble in nitroglycerin is said to render the material much more plastic, and to prevent cracking in drying.—W. M.

*Explosives [Flame extinguishing] applicable for Use in Coal or other Fiery Mines; Impts. in the Manufacture of.* W. J. Orsman, Gathurst. Eng. Pat. 22,698, Nov. 27, 1895.

THE object of this invention is to produce an explosive which shall liberate hydrochloric acid on detonation, but at the same time obviate the necessity of chlorinating the nitro compound serving as the combustible in the mixture. Naphthalene or some other easily attacked non-nitrated hydrocarbon is chlorinated. This highly chlorinated hydrocarbon is mixed cold in suitable proportions with ammonium nitrate and dinitrobenzene to produce an explosive.—W. M.

*Explosives [Safety], Impts. in or relating to.* W. Greaves and E. M. Hann, both of Aberaman, Glamorganshire. Eng. Pat. 24,847, Dec. 27, 1895.

THE object of this invention is to render safe and flameless, the explosives of the nitroglycerin and guncotton class, by the addition of either ammonium oxalate, tartrate, formate, or acetate, but preferably oxalate.—W. M.

*Explosives, Impts. in Apparatus [Vacuum Drier] for the Manufacture of.* H. F. Talbot, Birmingham. From O. Siedentopf, Berlin. Eng. Pat. 5640, March 13, 1896.

THE patent relates to a vacuum drier partially constructed with plates of a less strength than the body. In the event of explosion the former only are destroyed and can be readily replaced.—W. M.

*Explosives, Impts. in the Manufacture of.* W. P. Thompson. From "La Société des Explosifs Industriels." Paris. Eng. Pat. 20,069, Sept. 10, 1896.

THE object of this invention is to produce a shattering explosive by the addition of picric acid and naphthalene, potassium chlorate, tar and dinitrobenzene to gelatinous explosives composed of nitroglycerin and nitrocotton.

—W. M.

*Gunpowder, Smokeless.* F. A. Halsey and W. C. Savage, both of San Rafael, Marin, Cal., U.S.A. Eng. Pat. 22,120, Oct. 6, 1896.

A SMOKELESS gunpowder is described. Its composition for use in shot guns is: ammonium picrate, 68 per cent.; potassium bichromate, 25; and potassium or sodium permanganate or potassium pertungstate, 7 per cent.; but for rifles and other arms, the proportion of ammonium picrate may be increased and the other ingredients diminished.

—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

### APPARATUS, ETC.

#### PATENTS.

*Products of Combustion, A New or Improved Apparatus [Two Gas Meters] for Estimating the Carbonic Acid or other Constituents in Gases or.* G. Craig, Cumnock, Ayrshire, N.B. Eng. Pat. 22,303, Nov. 22, 1895.

THIS is an arrangement and combination of a gas-analysis apparatus comprising two gas meters, with a vessel containing material which shall absorb the constituent desired to be estimated in the gases passed from one meter to the other, and an aspirator, or suction pump, or ejector.

The first meter measures the original volume of gas taken, and the second, the balance of gas or product left, from which may be deduced the efficiency of combustion.

—L. J. de W.

*Specific Gravity, A New or Improved Apparatus for Separating Bodies of Different.* C. S. Meacham, Maidstone. Eng. Pat. 1177, Jan. 17, 1896.

THE apparatus consists of an exterior outer vessel which when in use is filled with water, an internal conical vessel having its sides perforated, and closed by a plug at the bottom, and a receiving tray which is placed beneath the plug-hole of the internal vessel. The apparatus is more particularly adapted for separating malt into the portion which sinks and the portion which floats in water. The measured portion of malt is thrown into the internal conical vessel and stirred up with the water; the sinking corns pass through the plug-hole and are caught in the receiving tray placed beneath; the floating corns remain in the internal vessel, and on inserting the plug can be withdrawn, the water draining away through the perforations.—A. L. S.

### INORGANIC CHEMISTRY.— QUANTITATIVE.

*Pyrophosphoric Acid, Estimation of.* Berthelot and G. André. Comptes rend., 123, 773—776.

DURING their researches on the phosphoric acids, the authors discovered that magnesium pyrophosphate usually carries down with it more or less magnesium, according to the conditions of precipitation. Instead of weighing the precipitate thus obtained, the authors redissolve it in dilute nitric acid and boil gently for an hour, thereby converting the pyrophosphoric acid into orthophosphoric acid, which can then be precipitated and weighed in the usual manner.

The analysis of a mixture containing pyro- and orthophosphoric acids is conducted in the following way:—The pyrophosphoric acid is first precipitated as magnesium pyrophosphate, which is redissolved and reprecipitated as indicated above. The filtrate from the first precipitation contains all the orthophosphoric acid; hence it is only necessary to concentrate the solution and precipitate as magnesium ammonium phosphate. Some test analyses are given, showing the accuracy of the method.—J. S.

*Borax, Commercial; Valuation of.* G. Heid. Zeits. f. ang. Chem. 1896, 679.

THE author determines gravimetrically, by precipitation with silver nitrate, the chlorine present in—

1. The original sample (5 grms.).
2. The residue (of sodium chloride and boric acid) obtained by boiling a solution of the sample (1 gm.) with an excess of hydrochloric acid, and evaporating to complete dryness. The difference between the results (1) and (2) represents chlorine equivalent to the sodium of the sample existing as borax.

—H. T. P.

*Gold and Silver, Estimation of, in Auriferous Minerals.* P. Truchot. Ann. Chim. anal. appliq. 1896, 1, 365.

100—200 GRMS. of the finely powdered ore are carefully roasted to expel sulphur, arsenic, &c., and are then digested for 36 hours with an excess of saturated bromine water. The solution is filtered off, acidified with hydrochloric acid, concentrated to about 200 c.c., again filtered, finally precipitated warm with an acid solution of ferrous sulphate, and the separated gold collected and weighed. The silver remains behind as bromide in the residue, from which gold has been removed, and may be extracted by means of a hot solution of ammonium chloride, and determined by known methods.—H. T. P.

*Lead, Volumetric Estimation of.* A. Longi and L. Bonavia. Gazz. chim. ital. 1896, 26, [1], 327.

THE authors have carefully tested some of the published methods. Domoite's process—precipitation with a titrated solution of sodium sulphide—is unsatisfactory on account of the indistinctness of the final point of reaction. Hempel precipitates the lead by ammonia and an excess of oxalic acid, and determines the excess of oxalic acid remaining in solution, or the combined acid in the precipitate, by titration with permanganate. This method yields results which are either too high or too low, according as the first or second variation is adopted. Better results are obtained when oxalic acid is determined in a precipitate formed under the following conditions:—The lead solution must not be too dilute, oxalic acid must be used in large excess, precipitation being made complete by an addition of alcohol, and finally the precipitate should be washed with the same liquid.—H. T. P.

*Tungsten from Titanium, Separation of.* E. Defaeqz. Comptes rend. 1896, 123, 823—824.

TUNGSTEN may be rapidly and completely separated from titanium by the following method, no matter whether the substances exist together in the free state as an alloy or in the state of oxides:—

The sample is ignited in a platinum crucible with seven or eight times its weight of a mixture of 8 parts of potassium nitrate and 2 parts of potassium carbonate at a dull red heat for 20 or 30 minutes. The fused white mass is treated with water, filtered, and washed, first by decantation and then on the filter with a solution of ammonium nitrate. The tungsten is estimated in the filtrate by precipitating as tungstate of mercury, whilst the residue, which contains the titanium, is dried, ignited, treated with potassium bisulphate, and the titanium estimated in the usual way.

In order to obtain good results, the fusion should not occupy more than one hour at the outside, and the temperature should not rise above dull redness.—J. S.

*Commercial Copper, Analysis of, by the Electrolytic Method.* A. HOLLARD. Comptes rend. 123, 1003—1005.

THE author adopts the following method for estimating, not only the copper, but also the impurities—arsenic, antimony, nickel, cobalt, &c.—in commercial copper:—

*Apparatus.*—A spiral of platinum wire and a truncated cone, each weighing about 20 grms., are the electrodes. The former is attached to a foot (Luekow). The latter is formed of platinum foil, autogenously soldered at its edges. Its diameter is 18 mm. above and 15 mm. below, and its side measures 63 mm. A rod of hard platinum is soldered with

gold to this truncated cone. Bohemian glass beakers, about 65 mm. diameter at the bottom, are used for the electrolyte.

*Method: Estimation of the Copper.*—10 grms. of clean filings, separated by a magnet from particles of iron, are used. These are placed in a beaker of 350—400 cc. capacity, covered with water, and 15 c.c. of sulphuric acid, followed by 40 c.c. of nitric acid of 36° B., are added. The author varies these proportions of acid, if a greater or less weight of copper is used for the analysis. The beaker is covered with an inverted funnel, and a gentle heat used when the first reaction has slackened. Refined copper yields a clear solution. Sulphur and sometimes oxygen compounds of antimony remain in unrefined copper solutions. If the latter residue be small it may be ignored. If considerable, it must be filtered off and the oxides dissolved by aqua regia. This solution is evaporated to dryness, taken up with hydrochloric acid containing tartaric acid and water, and is subsequently added to the original solution.

The copper solution is diluted to about 350 c.c. The electrodes are placed in it, the spiral connected to the + and the cone to the — poles of the battery. The distance between the lower edge of the cone and the foot of the spiral should be about 6 mm. The distance is increased or diminished, according to the amount of copper to be deposited. It must never exceed 10 mm. The upper edge of the cone must be 10—20 mm. below the surface of the solution. The vessel must be covered. The current must be 0.30 ampère. The completion of the removal of the copper is checked by withdrawal of a few c.c. of the solution and addition of ammonia solution. The author notes that the blue coloration is no longer visible, when the copper present is less than 0.017 gm. in the whole volume of the electrolyte. The current must be allowed to pass for some hours after this point is reached.

The complete deposition requires 2—3 days, with the current, and under the conditions named. The deposit is very adherent, has a smooth surface, and is of a rich red colour. The cone and spiral are removed from the electrolyte without breaking the current. They are washed by dipping successively into two beakers of distilled water. The cone is then immersed in alcohol, and, whilst still wet, placed in a drying oven. Silver is deposited with the copper. One must therefore deduct from the weight of copper, that of the silver subsequently found. If the copper used for analysis contain lead, this will be found partly in solution, and partly deposited as lead peroxide on the spiral.

In a future article, the author will deal with the exact determination of the impurities of commercial copper.

—J. B. C. K.

*Lead in Water, A Simple Method of Detecting and Estimating Minute Quantities of.* J. C. Berntrup. Chem. Zeit. 1896, 20, 1020.

THE author observes that reports from two chemists on a sample of water containing minute traces of lead will often be contradictory. The water may have been concentrated by one, but not by the other, before the sulphuretted hydrogen was passed through it. To secure the delicacy of the concentration method, and yet avoid its inconvenience, the author proposes to precipitate by an adequate quantity of sodium phosphate, the calcium and magnesium salts in the water. The precipitate contains also the lead. After settling for 24 hours, the supernatant liquid is siphoned off, and the precipitate is collected on a filter and dissolved in a little dilute nitric acid. The solution is concentrated to drive off excess of acid, and is then treated with sulphuretted hydrogen. The quantity of lead, if very minute, may at this stage be estimated colorimetrically, but if the precipitate be considerable, it is redissolved in nitric acid, and the lead is determined in the solution by one of the recognised methods, such as precipitation by sulphuric acid. Sulphuretted hydrogen was found to give a distinct coloration when applied according to the author's method to solutions containing 0.0001 and 0.000025 gm. of lead per litre. Two quantitative estimations in a solution containing 0.005 gm. of lead per 10 litres gave 0.0049 and 0.0041 gm. of lead. Before applying the method to very soft water, some solution of calcium chloride should be added to it.—J. A. B.

"Cap Composition," *The Analysis of*, F. W. Jones and F. A. Wilcox. *Chem. News*, 1896, **74**, 283.

THE authors describe a simple method for the analysis of "cap composition," which usually consists of a mixture of potassium chlorate, antimony sulphide, and mercury fulminate. It depends on the fact that the latter substance is soluble in acetone saturated with ammonia, whilst the two former are not. A tared filter paper is placed in a funnel, to the neck of which has been fitted a piece of rubber tubing provided with a clip. The paper is moistened with the solution of acetone and ammonia, the cap composition previously ground in an agate mortar (of course, with due care, and taking only small quantities at a time), weighed off directly on to the filter paper, covered with the solution of acetone and ammonia, and allowed to stand for 3 or 4 hours. It is then washed with the same solution until the washings give no coloration with ammonium sulphide, then with pure acetone until the washings give no residue on evaporation, and finally dried and weighed.

The paper is again put in the funnel, washed with water until free from potassium chlorate, and then dried and weighed.

The loss of weight after the first extraction gives the weight of mercury fulminate; the further loss after the second extraction, the weight of potassium chlorate; and the weight of the residue, that of antimony sulphide. The results of the analyses, by this method, of two mixtures of known composition, are given below:—

	A.		B.	
	Per-centage taken.	Per-centage found.	Per-centage taken.	Per-centage found.
Antimony sulphide .....	36.47	35.25	37.34	37.22
Potassium chlorate .....	33.25	33.71	46.03	46.13
Mercury fulminate .....	30.27	30.02	16.61	16.34

—A. S.

*Nitroso-β-Naphthol*, Use of, in *Inorganic Analysis*. R. Burgass. *Zeits. f. anorg. Chem.* 1896, [19], 596—601.

ACCORDING to the researches of the author on the action of nitrosonaphthol as a reagent with regard to the analytical separation of the most commonly occurring metals, the following results are worthy of notice:—

1. Nitrosonaphthol quantitatively precipitates, either singly or together, the following metals:—Cobalt, Copper, and Iron.

2. There remain in solution:—mercury, nickel, chromium, manganese, lead, zinc, aluminium, cadmium, magnesium, calcium, beryllium, antimony, and arsenic.

3. The following are partially precipitated, and so interfere in precipitations by means of nitrosonaphthol when they are present in a mixture:—silver, tin, and bismuth, and they must be first removed as silver chloride, stannic oxide, and bismuth oxychloride respectively.

4. In like manner, in the case of precipitations of iron, the presence of phosphoric acid is injurious, as is also that of tungstic and molybdic acid, when iron, cobalt, and copper are to be precipitated. (See this Journal, 1893, 711.)

—A. S.

## ORGANIC CHEMISTRY.—QUALITATIVE.

*Beer*, Detection of *Salicylic Acid* in. J. J. La Bière, **4**, [12], 182.

THE author in examining the distillate from pale and dark beers, found in every case, especially in the dark beers, that a red-violet coloration was produced with ferric chloride, and although the reaction is weaker if the distillation be performed by the aid of a paraffin bath instead of over a naked flame, and if two drops of concentrated sulphuric acid have been previously added per 100 c.c. of beer taken, it cannot be entirely eliminated. This source of error, can however, be avoided by the use of Millon's reagent (1 c.c. of mercury in 10 c.c. of concentrated nitric acid) freshly

prepared, two drops producing a decided rose-coloration in presence of as little as 1 part of salicylic acid in 500,000 parts of water. The addition of the sulphuric acid also facilitates the distillation of the salicylic acid. The red-violet coloration with ferric chloride is apparently due to the presence of maltol which exists ready formed in torrefied malt and dark beers, and is probably also formed by the overheating, inevitable at the end of the distillation of the beer. (See this Journal, 1894, 670, and 1891, 165).

—C. S.

*Ethylene and Benzene*, Estimation of. F. Haber and H. Oechelhäuser. *Ber.* 1896, **29**, 2700—2705.

THE authors uphold the statement made by Treadwell and Stokes (this Journal, 1889, 64), as to the utility of bromine water for the complete absorption of ethylene, and refute Winkler's conclusions (this Journal, 1889, 570), that although bromine water is rapid in its action, it is useless as an absorbent for ethylene in gas analysis. Winkler asserts that bromine water absorbs benzene incompletely: Trendwell and Stokes, however, found its action to be rapid and perfect. The authors detail experiments upon the absorption of benzene by bromine water, their object being to ascertain the extent of bromination, if any, or to determine whether the benzene is removed from the gas by mechanical means. For this purpose benzene was mixed with a measured quantity of standardised bromine water in such a manner, that the vapour of bromine was brought into intimate contact with the gas for about two minutes in diffused daylight. No loss of bromine was observed, the benzene being carried down mechanically with the bromine vapour. As a result of this work, the authors have devised a method of estimating the respective amounts of ethylene and benzene in mixtures of these gases. In the case of a mixture of ethylene, benzene vapour, and paraffins, the benzene is first separated by washing with paraffin oil, after which the bromine method can be employed.—D. B.

## ORGANIC CHEMISTRY.—QUANTITATIVE.

*Polarisation*, Basic Nitrate of Lead as a Clarifying Agent for. F. Herles. *Zeits. Zuckerind. Bohm.* 1896, **21**, 189—193.

THIS clarifying agent, proposed seven years ago by Herles, and since then highly praised by Poupe, Stift, Petzval, Neumann, and others as having a surprising decolorising power, has the further advantage that solutions clarified with it may be used directly for inversion polarisation without further decolorising by charcoal.

For this purpose, Herles determined the inversion constant which is higher than that for solutions not clarified, being 143.5 for 0° C. The Clerget formula takes then the following form:—

$$S = \frac{100P - 1}{143.5 - t}$$

For the determination of saccharose in presence of raffinose, from the polarisation at 20° C. of the inverted solution clarified as above—

$$S = \frac{0.5124 - I}{0.8474}$$

or for temperatures other than 20° C.—

$$S = \frac{(0.4724 + 0.002t)P - I}{0.7074 - 0.006t} \quad \text{and} \quad R = \frac{P - S}{1.85}$$

where S = sugar (saccharose), P = direct polarisation, I = polarisation after inversion, t = temperature of the inverted solution, R = anhydrous raffinose.

The two solutions required are:—*Alkali*.—2 litres of water and 90 grms. of sodium hydrate. *Nitrate of Lead*.—2 litres of water and 1 kilo. of nitrate of lead. For 26.048 grms., there are to be used: for molasses and osmose waters, 15 to 18 c.c.; for raw sugar, first products, 1 to 2 c.c.; for after products, 3 to 4 c.c.; for second and third products, hoiled, 12 to 15 c.c. of the nitrate of lead solution, to each c.c. of which 1 to 1.1 c.c. of the alkaline

solution is added. If more alkali is used than is necessary to form basic nitrate of lead, the polarisation is found too low, owing to the injurious action of the alkalinity. By using the proportions given, an excess of lead nitrate remains, which has no marked influence on either the direct polarisation or that after inversion, and which, on the contrary, neutralises the alkalinity of the clarified solution, and consequently prevents the error in polarisation due to this alkalinity. With the use of basic acetate of lead, which reacts alkaline, there is always risk of this error.

Solutions clarified by basic nitrate of lead, even when the nitrate has been employed in excess, may be used direct for inversion polarisation for which solutions clarified with excess of basic acetate of lead are not suitable, since, on adding the hydrochloric acid for inversion, weak acetic acid is set free, and the solution would not invert under the usual conditions of work.

Moreover, the polarisation of solutions clarified by this means gives more exact results than when basic acetate of lead is used. It is known that an excess redissolves a part of the precipitate formed, and as this may be optically active, the polarisation may be affected. (Degener, Berl. Zeits. 1885, 121.)

Neumann (Zeits. Zuckerind. Böhm. 1896—1897, 21) has found that with an excess of basic acetate of lead some molasses give lower and lower polarisations, and a darker colour of the solution was observed.

Solutions clarified by this means filter quickly and remain clear a longer time.

At the meeting of Austro-Hungarian chemists this year it was decided to use clarification by nitrate of lead for determining sugar in molasses by means of the Clerget inversion only, the solution for direct polarisation being clarified by basic acetate of lead. The author is of opinion that to obtain exact results, the nitrate should be used in both cases if his formula is to be employed.—L. J. de W.

*Molasses, Contributions to the Analysis of.* D. Loiseau. Bull. de l'Assoc. des Chim. de Sucre et de Dist. 1896, 14, 349—365.

REICHARDT and Bittmann named those substances "plus sugar," which are present in beetroot molasses derived from the strontia and other processes, which remain dextro-rotatory after treatment with hydrochloric acid.

In the author's investigations a polariscope was used, requiring a normal weight of 16.19 grms. A solution of molasses containing 20 times this weight, or 323.8 grms. per litre, is treated with an amount of basic lead acetate producing the maximum defecation. If, as is often the case, the solution is too dark to read, it is filtered, and decolorised by passing through a column of animal charcoal; the application of char being based on the fact that it continues to exert decolorising influence when saturated with sugar. The author finds that 200 grms. of char per litre of defecated molasses is generally enough for this purpose. In the event of the solution of molasses being very alkaline, it is neutralised before passing through the column. The flow is regulated by a tap, and successive portions are polarised until the readings are constant. An experiment showed that a solution of pure sugar when passed through a column of char successively read 76, 89, 96, 99, 100 per cent. Therefore, if 100 to 125 c.c. of the decolorised molasses per 100 grms. of char be neglected, it will be found that the remainder contains all the sugar.

It is pointed out that the usual methods of inversion act on substances other than raffinose and cane sugar, for example, the dextrins, and, as it is necessary to estimate these, it is recommended that the inversion be carried out in the following manner:—50 c.c. of the decolorised solution are measured into a flask with an equal volume of 19 per cent. sulphuric acid. The flask is shaken, closed with a rubber stopper, immersed in a bath of water at 50° C., and kept at this temperature for 1½ hours. Sometimes it is useful to take the reading of the defecated solution acidified with acetic acid before inversion, in order to nullify any effect arising from the use of basic lead acetate. It is advised that the tube should remain for 10 minutes at a temperature of 20° C before polarising, the results being checked before and after by reading

a tube containing a solution of pure invert sugar of known strength. After inverting at 50° C. and reading at 20°, the author finds a rotation of  $-0.34$  for cane sugar and  $+0.51$  for raffinose per saccharimetric degree. Therefore the difference between the reading of an inverted molasses solution, and that of a solution of pure sugar, which before inversion had a rotation equal to the defecated molasses, divided by the algebraic sum ( $0.85$ ) of the readings in scale divisions of raffinose and cane sugar after inversion, will give the rotation due to raffinose. For instance, the reading of a solution of molasses was  $50^\circ$  before inversion and  $-14^\circ$  after. A solution of pure sugar polarising  $50^\circ$  when inverted would read  $-17^\circ$ . This corresponds to a difference of  $3^\circ$ , and hence the rotation of the raffinose in the molasses will be  $\frac{3}{0.85} = 3.5^\circ$  and for sugar  $50^\circ - 3.5^\circ = 46.5^\circ$ . The coefficient  $0.85$  was found to vary with the temperature, thus at:—

$$15^\circ \text{ C} = 0.365 + 0.50 = 0.865$$

$$25^\circ \text{ C} = 0.315 + 0.52 = 0.835.$$

In studying the fermentation of molasses the author determines by preliminary experiment the quantity of 10 per cent. sulphuric acid necessary to invert a defecated molasses solution, under the conditions that, *firstly*, the inversion should commence at the temperature of the boiling water-bath, and *secondly* that it should be completed within five minutes. In one of the examples given, the quantity of acid necessary was 9 grms. of  $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$  for every 100 grms. of molasses. A volume of 400 c.c. is taken for fermentation, half of which consists of inverted molasses, and 8 grms. of top fermentation yeast; these quantities are introduced into a flask with a wide mouth, closed with a rubber stopper, and fitted with a bent tube dipping into mercury. It is kept at  $24^\circ$  to  $25^\circ$  C. for six to seven days, fermentation being considered at an end when two weighings of the flask and its contents within an interval of 24 hours are constant. The solution is filtered and the specific gravity, acidity, and content of alcohol determined. Should raffinose, dextrin, and saccharin be sought for, the following cases present themselves. 1. If the solution has no specific rotatory power, raffinose is absent. 2. If it has a dextro rotation and does not reduce Fehling's solution, raffinose is absent, but other substances such as dextrin and saccharin are present. If there should be a reduction, it arises from the presence of derivatives of noncrystallisable sugar in the molasses. 3. If the solution has a rotation of  $2.5^\circ$  and reduces Fehling's solution to the extent of 1 grm. of glucose to a litre of solution, raffinose may be considered to be present; but if the rotation be higher for the same reducing power, a dextrin and saccharin are also present. It is necessary to know whether the substances with rotatory power remaining in the solution after fermentation were pre-existent or due to raffinose; this can be ascertained by fermenting with bottom fermentation yeast, in which case dextrin and saccharin remain unaltered. The author carries out this determination by taking the de-alcoholised fermentation product, and making up to the original volume with water. One-third is fermented afresh with top-, the remainder with bottom-fermentation yeast. When fermentation is ended, each solution is polarised; if the reading of the latter be lower than that of the former, the difference divided by  $0.785$  is the rotation of the raffinose. To distinguish between saccharin and dextrin, the bottom yeast fermentation experiment is concentrated to one-half, and when cool made up to the original volume with 10 per cent. sulphuric acid, and boiled for three hours. If no glucose is formed saccharin only is present; but should there be glucose, a fresh fermentation will reveal the existence of any other substance not attacked by acid.—J. L. B.

*Molasses, The Clarification of Solutions of, for Inversion.* K. C. Neumann. Zeits. Zuckerind. Böhmen, 1896, 21, 183—188.

In the laboratory of Dr. Nevole and Neumann basic nitrate of lead has been used to clarify solutions of molasses, during the past five years, in determining the sugar by the Clerget method, and thereby perfectly clear solutions are

obtained which can be polarised without further decolorising. For the calculation, the direct polarisation is made on solutions clarified by basic acetate of lead, and the polarisation after inversion, by nitrate of lead, and Herles' constants are used.

He finds that the polarisation of the filtrate from the nitrate seldom agrees with that from basic acetate of lead, and is usually 0.6 to 0.8 per cent. higher. Finding that a number of samples of molasses from a factory working the strontian process gave a lower direct polarisation than with the acetate, he mixed the rest of the samples for further examination.

The liquid was of normal colour and smell, feebly alkaline (0.09 per cent. to litmus), and contained only 0.29 per cent. of invert sugar.

By clarifying with varying amounts of basic acetate of lead (from 2.5 to 20 c.c.), polarisations were obtained varying from 63.7 to 61.5 per cent., the usual 10 c.c. of acetate giving 62.6 per cent.

The variations with the nitrate of lead varied somewhat with the amount of alkali added.

After inversion, the dark half normal solution was treated with 6 grms. of char for half-an-hour and then gave at 20° C. in the 200 mm. tube -3.6, -3.8, -4.0 or an average of -3.8, a very uncertain reading.

The solution clarified with basic nitrate of lead was, after inversion by hydrochloric acid, very clear and easily polarised, giving -4.50, -4.45, and -4.40.

Calculations were then made from the data obtained.

Result A by the basic acetate of lead, using Clerget's formula and the factor 142.7.

Result B by basic nitrate of lead, using Herles' formula and the factor 143.5.

Result C by basic acetate for the direct polarisation and basic nitrate of lead for the inversion polarisation, and the factor 143.5.

	C.	B.	A.
Polarisation ....	62.60	62.45	62.60

Cane-sugar .....	48.49	48.41	47.29
Raffinose .....	7.62	7.59	8.27

The results B and C being thus in accord.—L. J. de W.

*Raw Sugar Factories, Collated Methods of Analysis for the Control and Working of.* Feleman, K. C. Neumann, and F. Herles. Bull. de l'Assoc. des Chim. de Sucr. et de Dist. 1896, 14, 392—405.

THIS paper consists of descriptions of sample-collecting and analysis of materials dealt with in a raw-sugar manufactory, and comprising diffusion, saturation, filter-press work, evaporation, and the control of the massecuite. Diffusion juice, when collected hot, will keep for some hours; but, if it is required to be kept for a longer time, a convenient preservative is 10 c.c. of carbon bisulphide per litre of juice. The solution should be polarised immediately after filtration, as otherwise it clouds in the polarimetric tube.

The sugar in fresh and exhausted cosettes is determined by placing the required weight of pulp free from large pieces in a graduated Pellet's flask by the aid of a nickel funnel and rod. The funnel is rinsed with hot water and the flask three-quarters filled with water at 90° C. and agitated by shaking over on end. The froth is removed by alcohol; and for every 26.048 grms. of pulp, 4 or 5 c.c. of basic lead acetate are added, and the flask filled up to the containing mark with hot water. The contents of the flask are revolved, allowed to settle for 15 minutes, cooled to the temperature of the surrounding atmosphere, and filled up to the requisite volume with water or lead acetate. After being shaken vigorously, the solution is filtered and polarised, a correction being made for the volume occupied by the pulp. In the examination of exhausted cosettes, it is recommended to polarise in a 400 m.m. tube.

A convenient and sufficiently accurate method for calculating the percentage of froth in the first and second

saturation, is to multiply the parts per 100 of dry lime used, by four.

In the massecuite-control, the amount of sugar indicated by analysis is not realised owing to losses occurring during the concentration and evaporation. These, which are called indeterminate losses, do not vary much in different factories. The presence of sugar in the condensation waters, occasions considerable damage to the heaters, &c., and it should be tested for at least twice a day by the magenta test.

The authors, in conclusion, point out that the control calculations should be made out every 24 hours.—J. L. B.

*Massecuites, Determination of Density of.* St. Tirpitz. Bull. de l'Assoc. des Chim. de Sucr. et de Dist. 1896, 14, 372—374.

THE author proposes that a temperature of 105°—107° C. should be employed to estimate the water in massecuites, which should be mixed with purified pumice, the individual grains being the size of sand.

For the determination of the direct density of the massecuite, a thick walled cylindrical stoppered glass vessel of a litre capacity is recommended, it being urged that the method of dilution so commonly practised, is incorrect.

—J. L. B.

*Sugar, A New Method for the direct Estimation of, in the Beetroot by the Le Docte Apparatus.* F. Sachs. Bull. de l'Assoc. des Chim. de Sucr. et de Dist. 1896, 14, 377—382.

OF the three methods of extraction, namely, the indirect method based on the analysis of the juice, and the alcoholic and aqueous methods, the author considers the last mentioned to be the most satisfactory.

The Le Docte apparatus consists of a pipette, having at the bottom a three-way tap, connected with reservoirs of basic lead acetate and water, the third tube serving as an exit for the contents. The water and lead acetate being introduced from below, the top of the pipette is surrounded with a closed cap in case of an overflow. 5 c.c. of basic lead acetate are run in and the apparatus filled up with water to its containing mark (177 c.c.). The normal weight of pulp is directly weighed into a tinned copper capsule, the contents of the pipette added, and the capsule covered with a cap, consisting of a piece of glass surrounded with well vaselined rubber. After shaking, the cap is carefully removed by drawing it along the edge of the capsule; the contents are then filtered and polarised.—J. L. B.

*Invert Sugar, the Influence of Lead Salts on the Estimation of, by the Fehling-Sorhlet Method.* A. Bornträger. Bull. de l'Assoc. des Chim. de Sucr. et de Dist. 1896, 14, 453.

AN examination of solutions of invert sugar of varying concentrations, with or without dilutions of the copper solution, has shown that the results are much lower in the presence of lead salts. This influence is considerably augmented by dilution. In the analysis of wines, the author found it useless to precipitate the excess of lead, unless more than  $\frac{1}{10}$ th the volume of liquid consisted of basic lead acetate. For precipitation, either phosphate or carbonate of sodium is preferable to the sulphate.—J. L. B.

*Alcohol, the Estimation of.* H. D. Richmond. J. Fed. Inst. Brewing, 1896, 2, 529—535.

ACCORDING to Tabarie the density of alcohol in a liquid is found by dividing the density of the liquid by that of the non-volatile portion or "extract." Blunt has shown that more correct results are obtained if the density of the extract be subtracted from that of the liquid plus that of water. It is generally agreed that Tabarie's method is theoretically correct; the author, however, shows from mathematical considerations, Blunt's proposition to be the true one. When the determination of the density does not yield sufficiently accurate results, the following method, based on that of Hehner, for the detection of methyl alcohol, which was derived from that of Dupré, may be used. It depends on the equation—

The liquid to be examined is distilled in the usual manner, with or without the addition of water. A quantity of the distillate, containing from 0.2 to 0.3 gm. of alcohol, is diluted to about 100 c.c., and placed in a stoppered bottle; about 1.5 gm. of potassium bichromate accurately weighed, and 5 c.c. of strong sulphuric acid are added to the liquid. The bottle is placed in water, which should be gradually raised to the boiling-point, and frequently shaken until the bichromate is dissolved. The boiling should be continued for two hours with occasional shaking; it is then allowed to cool slightly, the stopper removed, and a 7 to 8 per cent. solution of ferrous sulphate, containing 10 c.c. per litre of sulphuric acid, is run in from a burette, until a drop of the solution forms a blue coloration with potassium ferrocyanide. The excess of ferrous sulphate is titrated back with a dilute solution of potassium bichromate (5 grms. per litre). The ferrous sulphate solution should be standardised upon the dilute bichromate solution, and the quantity of ferrous sulphate solution added, calculated to its equivalent of bichromate; the amount of bichromate used during the back titration is added to the original amount, and the quantity equivalent to the ferrous sulphate solution used is subtracted from this; the difference divided by 4.278 will give the amount of alcohol.

A solution containing 42.78 grms. of potassium bichromate per litre may be used instead of weighing out the bichromate, and this diluted 10 times, can be employed for the back titration.

This method affords good results if the conditions are adhered to, the amount of sulphuric acid and time of heating being important.

As a check, the acetic acid may be estimated; the solution obtained after titration is placed in a flask and distilled down to 15 c.c., successive portions of 15 c.c. of well-boiled water are added, and 15 c.c. distilled off each time, till the distillate does not require more than two drops of  $\frac{1}{10}$  N alkali to render it alkaline; the collected distillate is neutralised with caustic soda solution, to which a little baryta has been added; the amount of caustic soda used cannot, however, be taken as indicating the amount of acetic acid, since sulphuric acid is always found in the distillate; if the bulk of liquid be very large, it is advisable to concentrate it at this stage. A quantity of dilute and well-boiled sulphuric acid is added to the concentrated neutralised solution, which should then be distilled to a small bulk; portions of 10 c.c. of boiled water are successively added and distilled off until the distillate is neutral. The mixed distillate should then be titrated with  $\frac{1}{10}$  N alkali, using phenolphthalein as indicator. The acetic acid found is calculated to alcohol by dividing by 1.3043.

If the two determinations agree closely it may be taken as evidence that methyl alcohol is absent, since this alcohol gives no volatile fatty acid, being completely oxidised to carbon dioxide and water.

To show that higher alcohols are absent, Duclaux's method may be employed. When the distillate containing the volatile acid has been neutralised and concentrated, and there has been added a measured quantity of sulphuric acid, slightly in excess of the quantity equivalent to the alkali used for neutralisation, it is diluted to 110 c.c. This is placed in a stoppered distillation flask the upper part of which is surrounded with a jacket of copper-piping. The liquid is then heated nearly to boiling and steam passed through the coil; the liquid should then be distilled, and when 10 fractions of 10 c.c. each have been collected, portions of 10 c.c. of boiled water are added and successively distilled off. Each fraction (the whole of the distillate after the water is added should be collected and treated as one fraction) is titrated separately, and the amounts noted. It is advisable to neglect the first fraction, and add the amount of acid obtained in the other 10 together to obtain the total quantity for the purposes of calculation. Taking this as 100, the quantity of acid in each fraction should be calculated as a percentage of this. Calling the percentage distilled  $x$ , and the percentage of total acid in that quantity  $y$ , the amount in the distillate at any point is expressed by

the formula  $100 - y = \frac{100(100 - x^2)}{100}$ ,—J. L. B.

*Critical Temperatures of Solution [Butter Analysis] in Open Tubes.* L. Crismer. Bull. Assoc. Belge des Chimistes, 10, [8], 312—316.

For butter analysis, the operation can be performed in open test-tubes surrounded by an air- or water-bath, provided absolute alcohol be employed, the critical temperature in such case ( $48^\circ\text{C.}$ ) being lower than the boiling point of the solvent. With dilute alcohol the temperature increases parallel with the proportion of water present, *viz.*,  $72^\circ\text{C.}$  with 4 per cent.,  $82.5^\circ\text{C.}$  with 6 per cent.,  $99^\circ\text{C.}$  with 9 per cent. of water, and so on.

The most suitable quantities to work with are 2 vols. of alcohol to 1 of butter (about  $\frac{1}{2}$  c.c.), the temperature remaining constant between the limits of  $1\frac{1}{2}$  and 3 vols. of alcohol. Heat is applied by a small flame, with agitation, and as soon as the liquid becomes homogeneous it is cooled until turbidity ensues, the temperature at this point being noted. The test is repeated as before, after addition of a small quantity of alcohol, as a check on the first determination.

The average critical temperature of a number of samples of pure butter, with alcohol of sp. gr. 0.7967 at  $15.5^\circ\text{C.}$  ( $= 0.9$  per cent. of water) was  $54^\circ$  to  $55^\circ\text{C.}$ , whereas margarine and adulterated butters ranged from  $63.8^\circ$  to  $78^\circ\text{C.}$ , the temperatures obtained in sealed tubes, with alcohol containing 9 per cent. of water, being respectively *circa*  $100^\circ\text{C.}$  and  $120^\circ$  to  $124^\circ\text{C.}$

Some pure butters give lower temperatures, but this is owing to rancidity or acidity (due to preparation from sour cream), the normal temperature being obtained after purification. It is noted as curious that the number of c.c. of  $\frac{1}{25}$  N KHO required to neutralise the acidity, when added to the critical temperature of the acid butter, gives figures closely approximating to the critical temperature of the purified butter. This temperature (for pure butter) varies inversely with the degree of acidity, and therefore affords a direct indication of the latter and of the care taken in preparing the butter.—C. S.

*Quinine, Note on the Estimation of.* D. Howard. Pharm. J. 1896, 565.

In spite of the great difference in solubility between the sulphates of quinine and of the other alkaloids, and of the ready crystallisation from ether, of cinchonidine, cinchonine, and quinidine, the ease with which quinine and cinchonidine form more or less definite compounds when crystallising as sulphates from water or as bases from ether, makes the problem difficult. Liebig's test—shaking with ammonia and ether—will pass as pure, a sample containing 10 per cent. of cinchonidine sulphate. Kerner's ammonia test, which in its different modifications is the most widely adopted, can only give empirical results, because of the difficulty of dissolving out cinchonidine sulphate when crystallised with quinine sulphate, and this difficulty is increased by the non-homogeneity of the crystals deposited from an impure solution of quinine sulphate, the composition varying with the temperature. If the strong solution be slowly cooled, nearly pure quinine sulphate is deposited above  $50^\circ\text{C.}$ ; below that temperature, mixtures with cinchonidine sulphate in increasing proportion separate. Thus, when the solution for the ammonia test is made by shaking with cold water, as prescribed in Ph. Ger. II., a solution of the outside of the crystals being obtained, the more rapidly the salt has been crystallised in the factory, the purer it will appear to be. To obviate this difficulty the crystals may be effloresced by heating, as in the U.S. Ph., or the sulphate may be digested with hot water and the mixture allowed to cool, with frequent shaking. Hesse and Weller have shown that  $60^\circ\text{C.}$  is the best temperature for this digestion; if the salt be entirely dissolved, all the difficulties of the uncertainty of the composition of the salt deposited are intensified. If a boiling solution of sulphate of quinine be saturated with the free alkaloid, on cooling, part of the latter separates with the sulphate; the solution left and the solution of the sulphate deposited will both require much more ammonia to redissolve separated quinine than the neutral salt requires. A very small quantity of ammonium or sodium sulphate greatly diminishes the solubility of quinine sulphate.

The method proposed by Kubli (this Journal, 1896, 681) has no advantages over the older method (Hesse, Arch. Pharm. 234, 191, see following abstract; also Weller, Pharm. Zeit. 1896, No. 28).

In regard to the ether test, Premier has shown that if a solution of impure quinine sulphate be cooled to 50° C., and kept at that temperature for some time, with frequent shaking, most of the quinine crystallises out, and if the liquid be filtered at 50° C., the solution will contain within 2 per cent. of the total cinchonidine. If this solution be evaporated to a small bulk and the magma be shaken with just enough ether and ammonia to produce momentary solution, crystals form, which in amount are in a definite ratio to the cinchonidine in the original sample, though they do not contain the whole of this alkaloid. If these crystals amount to more than 2 per cent. of the original sulphate, the process of crystallisation at 50° C. must be repeated. In the author's experience this process is on the whole more reliable than the ammonia test.

In the method of De Vrij and Hesse, which depends on crystallising the quinine as far as possible as bisulphate and estimating the cinchonidine in the mother-liquor by shaking with ether and ammonia, owing to the large amount of quinine still remaining in solution, the cinchonidine will remain to a great extent in the ethereal solution. Thus, to obtain accurate results, a sufficient quantity of the sample must be used to permit of the mother-liquor from the first batch of crystals being concentrated and again crystallised, before extraction of cinchonidine from the second mother-liquor. In a complete analysis, the impure cinchonidine obtained, is dissolved in absolute alcohol and 2.1 c.c. of 50 per cent. sulphuric acid added for each grm. of crystals; the cinchonidine crystallises out almost entirely as tetrasulphate, and, on neutralising the mother-liquor and evaporating, the quinine is obtained as sulphate. The ethereal solution containing cinchonidine should be evaporated, the alkaloid crystallised as bisulphate, and the mother-liquor again treated with ether and ammonia. These last operations are generally unnecessary in practice, for, with care, the quinine crystallising with the cinchonidine very nearly balances the cinchonidine dissolved by the ethereal quinine solution. If it be required to estimate the hydroquinine generally found to the extent of 2-4 per cent. in commercial samples, the alkaloid in the ethereal solution is dissolved in dilute sulphuric acid and oxidised at 0° C. by 4 per cent. permanganate added drop by drop till the solution when filtered is only slowly decolorised. The manganese oxide is filtered and washed, the solution treated with ether and ammonia, the alkaloid extracted from the ether by dilute sulphuric acid, the solution neutralised and crystallised. No indication of the presence of hydroquinine is given by the ether test.

The ammonia test offers great advantages as a test for pure quinine sulphate; it is, however, very doubtful if it is wise to insist on the use of the pure salt in pharmacy.

—A. C. W.

#### Quinine Sulphate, Analysis of. O. Hesse. Arch. der Pharm. 1896, 234, 191.

An examination of the tests proposed by Kubli (this Journal, 1896, 681).

**The Water Test.**—In preparing the solution for this test the author finds that the duration of the boiling has no influence on the result; it should therefore be prolonged to complete solution. In order to obtain comparable results by this method it is necessary to use a salt completely effloresced. In place of the 10 c.c. of water required to destroy the opalescence, in the case of Russian quinine sulphate, 11.5, 15, and 16.5 c.c. were required.

**The Carbonic Acid Test.**—The results obtained by this test do not agree with results obtained by the official processes, which latter agree among themselves. Thus the test is wanting in accuracy, and cannot control the water test. However, the two processes may be used as a test for a pure sample, but not to give a measure of any impurity.

—A. C. W.

#### Theobromine in Preparations of Cocoa, Determination of. A. Eminger. Apotheker Zeit. 1896, 716.

One part of theobromine dissolves in 736.5 parts of water at 10°, in 136 at 100° C., in 5,399 parts of 90 per cent. alcohol at 18° C., in 440 on boiling, in 818 of boiling absolute alcohol, in 21,000 of ether at 17°, in 4,856 of methyl alcohol at 18°, in 5,808 of chloroform at 18°, and in 2,710 parts of boiling chloroform. Theobromine is completely insoluble in carbon tetrachloride. It cannot be left in contact without alteration with the alkaline earths, the alkalis, or hydrated oxide of lead.

The author proposes to make use of the different behaviour of caffeine and theobromine on heating, to separate the two substances; caffeine melts at 178° and sublimes at 180°, whilst theobromine sublimes at 220° C. without melting. In the following method the insolubility of theobromine in carbon tetrachloride at 18° C. is made use of. 10 grms. of the powdered substance are left in contact with 150 c.c. of petroleum ether for 12 hours, with frequent shaking; the fat extracted contains no caffeine. The residue is dried, 5 grms. are boiled with 100 grms. of 3 to 1 per cent. sulphuric acid with a reflux condenser for about half an hour, until the characteristic cocoa red is formed. After exact neutralisation with baryta water, the residue is evaporated together with sand, and the residue extracted by chloroform for five hours in a Soxhlet apparatus. After distilling off the solvent, the residue is dried at 100° for one hour, and then treated with carbon tetrachloride (not more than 100 grms.) for one hour, with frequent shaking; fat and caffeine dissolve, the solution is evaporated, the residue extracted by boiling water, and the aqueous extract evaporated in a tared dish. The theobromine remaining in the flask, and the filter through which the carbon tetrachloride has passed, are boiled with water, the liquid filtered, the residue washed, the solution evaporated, and the theobromine weighed.

In different samples of cocoa, the following amounts have been found:—

	Theobromine.	Caffeine.
	Per Cent.	Per Cent.

#### Carbon and Nitrogen in Organic Compounds, Estimation of, in the Wet Way. P. Fritsch. Annalen, 1896, 294, 79-88.

The author has experimented with a view to combining, in the analysis of organic compounds, the Messinger wet combustion method for estimating carbon with the Kjeldahl-Krüger method of nitrogen estimation. He finds that oxidation with strong sulphuric acid and potassium bichromate, yields good carbon determinations when the apparatus is so arranged that the powdered bichromate can be added in very small quantities at a time. This is effected by the addition of a side tube on the air-inlet tube of the boiling flask, the tube containing the powdered substance being attached to this side tube by india-rubber tubing. The residue in the oxidation flask can at once be used for determining the nitrogen as ammonia by boiling with potash in the case of amides, ammonium bases, pyridine, quinoline, and indole derivatives, alkaloids, bitter principles, albuminoids, and similar substances; it cannot, however, be

satisfactorily used with nitro- or nitroso-compounds or nitrates, the methods proposed for previous reduction of the oxy-nitrogen groups all proving unsatisfactory.—L. T. T.

## XXIV.—SCIENTIFIC & TECHNICAL NOTES.

*Glucina, Properties of Pure.* P. Lebeau. *Comptes rend.* 1896. **123**, 818—821.

The author finds that pure glucina is fusible and volatile at the temperature of the electric furnace. When fused it does not vary sensibly in density, and retains the property of being attacked by concentrated acids. Boron, silicon, and carbon are capable of reducing glucina, giving crystalline compounds; whilst sodium, potassium, magnesium, and aluminium have no action on it.—J. S.

*Nitric Oxide, Absorption by Ferrous Bromide.* V. Thomas. *Comptes rend.* **123**, 943—945.

Ferrous salts have long been known to absorb large quantities of nitric oxide. The classic researches of Peligot proved that most probably a definite compound was formed; but he could not separate it. Recently Gay has confirmed Peligot's work; and, using the sulphate, the double ammoniacal sulphate, and the chloride of iron, he has proved that these salts absorb nitric oxide in two definite proportions, according to the temperature.

The author has undertaken a continuation of these researches, using ferrous bromide in aqueous solution, and gives, in his original communication, details of his method. He has proved that below 10° C., ferrous bromide absorbs nitric oxide, with the formation of a compound having the formula  $6\text{FeBr}_2 \cdot 4\text{NO}$ ; and that above 10° C. (15°—16°), an absorption of nitric oxide occurs, corresponding to the formula  $2\text{FeBr}_2 \cdot \text{NO}$ . These results confirm those of Gay.—J. B. C. K.

*Nitrogen, The Fixation of, by Algae and Bacteria.* R. Bonilhar. *Comptes rend.* 1896, **123**, 828—830.

From experiments the author finds that *Schizothrix lardacea* and *Ulothrix flaccida* cannot grow in nutritive solutions which are free from nitrogen, even in the presence of bacteria of the soil. In the case of *Nostoc punctiforme*, however, it is otherwise. The association of this alga with bacteria allows of the simultaneous development of both species with fixation of nitrogen. According to the analyses, the amount of nitrogen fixed by this plant is comparable with the amount fixed by the Leguminosæ. As in the case of *Nostoc*, bacteria capable of fixing nitrogen can live in solutions of arsenic acid containing 1 part in 10,000.—J. S.

*Jalap Tubers, Cinchona Plants, &c.: Beneficial Effect of Judicious Manuring on the Production of Essential Principles.* D. Hooper. *Indian Pharmacologist*, 1896, **1**, 89.

For many years the jalap plant (*Ipomœa purga*) has been successfully cultivated in the Government cinchona plantations at Dodabetta, Nilgiris, but about two years ago it was found that the plants were in an unhealthy condition, the tubers small and containing only 12.9 per cent. of resin; some tubers transferred to a freshly manured soil contained after some months 15.3 cent., and a large tuber grown near a manure heap contained 22 per cent. of resin—the largest yield on record. The soil of the Nilgiris is deficient in lime and phosphoric acid, the addition of which has always been beneficial to the local tea, coffee, and cinchona estates. Experiments were undertaken to observe the action of these substances on the growth of jalap tubers. The results demonstrated that the application of phosphatic manures largely increases the weight of the tubers, and raises the proportion of the active principle.

The question of manuring is one of great importance in cultivating plants for the purpose of increasing their active principles. It has been proved over and over again in cinchona culture, that nitrogenous and phosphatic manures increase the amount of alkaloids in the bark; in the same way, potash is good for tobacco crops; magnesia and lime for the sugar cane. There is no doubt that better results

would be obtained in growing medicinal plants if attention were directed to a proper system of applying suitable fertilising agents to the crops.—A. C. W.

*Strophanthus Hispidus, Oil of the Seeds of.* A. Mjoen, *Arch. der Pharm.* **234**, 283.

This oil, of a strong green colour, has the density 0.928; it gives on saponification:—formic, acetic, palmitic, and oleic acids, and glycerin.—A. C. W.

## New Books.

TABLES FOR THE QUANTITATIVE ESTIMATION OF THE SUGARS. With Explanatory Notes. By Dr. ERNST WEIN. Translated, with Additions, by WILLIAM FREW, Ph.D. E. and F. N. Spon, London. Spon and Chamberlain, New York. 1896. Price 6s.

8vo volume, containing preface to this, the English edition, table of contents, and text filling 128 pages. There is a frontispiece representing a Soxhlet tube (filled) drawn to scale. The little work contains the following items:—Description of Method for the Estimation of Sugars. Note on Alternative Method, and Preparation of Solutions. The tables have reference to the following subjects:—I. Estimation of Dextrose. II. Of Maltose. III. Of Milk Sugar; and IV. Of Invert Sugar (*Meissl*). V., VI., and VII. Estimation of Invert Sugar in presence of Cane Sugar (*Meissl*). VIII. Estimation of Invert Sugar in Beet Sugar (*Herzfeld*). IX. Estimation of Invert Sugar (*Lehmann*). X. Of Levulose; and XI. Of Starch. XII. Volumetric Estimation of Dextrose (*Reischauer*); and XIII. Of Maltose (*Reischauer*).

LUBRICATING OILS, FATS, AND GREASES: Their Origin, Preparation, Properties, Uses, and Analysis. By GEORGE H. HURST. Scott, Greenwood, and Co., Ludgate Hill, London. 1896. Price 10s. 6d.

8vo volume, containing frontispiece, preface, table of contents, and subject-matter filling 301 pages, four pages of tables, and an alphabetical index. The work is illustrated with 65 wood-cut illustrations.

The text is divided into eight chapters, devoted as follows:—

I. Introductory, Oils and Fats, Fatty Oils, Hydrocarbon Oils, Uses of Oils. II. Hydrocarbon Oils. III. Scotch Shale Oils. IV. Petroleum. V. Vegetable and Animal Oils. VI. Testing and Adulteration of Oils. VII. Lubricating Greases. VIII. Lubrication.

## Trade Report.

### PRIZES.

#### DR. NOBEL'S BEQUEST TO SCIENCE.

The *Paris Figaro* of the 7th January 1897 states that the only valid will is that written and signed in Paris by Mr. Nobel on the 27th November 1895 in the presence of four of his co-patriots, and opened at Stockholm on the 30th December last, which, in addition to legacies to about 20 of his relatives, friends, and servants, contains the following provisions:—

"All the remainder of my realisable fortune shall be disposed of as follows:—

"The capital realised and invested in safe securities by the liquidators was constituted, of which the interest shall be annually distributed to those who, during the past year, shall have rendered the most eminent services to humanity. The interest shall be divided into five equal parts, and shall be distributed:—

"The first to the one who in the domain of physics shall have made the most important discovery or improvement:

"The second to the one who in the domain of chemistry shall have made the most important discovery or improvement:

"The third to the one who will have made the most important discovery in the domain of physiology and medicine:

"The fourth to the one who in the domain of literature will have produced the work highest in the ideal sense:

"The fifth for the one who shall have acted most and best for the fraternity of nations, for the suppression or reduction of standing armies, and the constitution and propagation of peace congresses.

"The first two prizes (physics and chemistry) shall be awarded by the Academy of Sciences of Sweden, that for physiology and medicine by the Carolin Institute of Stockholm, and the literary prize by the Swedish Academy; and that for the propagation of peace by a commission of five members elected by the Norwegian Diet (Storting).

"It is my express wish that in distributing these prizes no consideration of nationality shall prevail, so that he who is most worthy of it shall receive the reward whether he be Scandinavian or not."

## TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

NETHERLANDS—GUIANA.

Regulations as to Methylated Spirits of Local Manufacture.

A report has been received from H.M. Consul at Paramaribo, stating that owing to the practice amongst the natives of using methylated spirits of local manufacture as stimulants, the mixture of a mineral methylic alcohol with the methylated spirits manufactured there has now become compulsory. The authorised methylators—methylic alcohol and benzine—are now exempt from import and excise duty.

## GENERAL TRADE NOTES.

ACETYLENE REGULATIONS IN PARIS.

*J. Gas Lighting*, Dec. 22, 1896, 68, 1230.

According to some provisional regulations lately issued by the Prefect of Police in Paris, manufactories of carbide of calcium and of acetylene compressed to more than  $1\frac{1}{2}$  atmospheres, or liquefied, are to be placed in the first class of dangerous buildings. Manufactories of acetylene gas not compressed, or compressed to less than  $1\frac{1}{2}$  atmospheres, if for public use, are to be in the first class; if for private use, in the third class.

ALCOHOL IN CANADA.

*Chem. and Druggist*, Jan. 2, 1897, 6.

Canadian alcohol costs about 1.15 dols. per gall. The same stuff can be obtained in the United States at 35 cents a gall. The reason for the higher price of the Canadian spirit is that the excise duty is 2.80½ dols. per gallon, and the import duty 3.71¼ dols. The drug trade of Canada (we learn from the *Canadian Druggist*) do not like this, and have appealed to the Tariff Commissioners to adjust the matter, thinking that 20 per cent. *ad val.* duty instead of 250 per cent. is quite enough protection.

ALUMINIUM AS A CONDUCTOR OF ELECTRICITY.

*Eng. and Mining J.*, Dec. 19, 1896, 581.

The new plant of the Pittsburgh Reduction Company, at Niagara Falls, known as the "Lower Works," located on the high bank of the river below the Falls, has been started. The Pittsburgh Reduction Company resolved to use aluminium rods or cables instead of copper for conducting the current from the generators in the power-house down in the gorge, some 200 ft. below, to the plant on the top of the bank. These rods are each  $\frac{3}{8}$  in. in diameter and 350 ft. long from the generators to the main line in the furnace room. These main line conductors, which traverse the pot room, are from 12 to 16 ins. wide and 1 in. thick, and are also of aluminium.

A CHEMICAL PLANT AT NIAGARA.

*Eng. and Mining J.*, Dec. 19, 1896, 581.

The new plant of the Mathieson Alkali Company, to be erected at Niagara Falls, will consist of several buildings covering 2 acres. The first section is to be completed by January 15th, 1897. The company which, as is well known, manufactures caustic soda by the Castner process, will employ 150 men and use 2,000 h.p. at its new works. It already has large plants in England and at Saltville, in Virginia. At the latter plant no water power is available. A very complete electric plant for the chemical process and for lighting is installed, Westinghouse apparatus being used.

THE RISE OF CHEMICAL INDUSTRY IN RUSSIA.

*Chem. and Druggist*, Jan. 9, 1897, 56.

Some time ago the Russian Ministry of Finance had under consideration a project for reducing or abolishing the duties on all drugs and pharmaceutical preparations that are not, or cannot conveniently be, produced in Russia. This scheme, if carried into effect, would give a much-needed stimulus to our export trade with that empire, which, so far as drugs and chemicals are concerned, has long been languishing. Some portion of the export trade in crude drugs formerly done between Britain and Russia has been transferred to continental ports, another to the countries of production themselves. Heavy chemicals, such as bleaching-powder and other alkalies, for which Russia used to be one of our best customers, are now made in that country itself, to an ever-increasing extent. The result is seen in our Board of Trade statistics of alkali exports to Russia, which show dwindling figures year by year.

In Germany, the importance of Russia as a buying market is quite appreciated. The tariff war of 1892-93 seriously dislocated the business relations between the two countries, but since the conclusion of the new Russo-German commercial treaty, German exports to Russia have reached a higher figure than ever before. The value of goods sent from Germany to Russia, converted into millions of pounds, was:—

1889.	1890.	1891.	1892.	1893.	1894.	1895.
£ 8.70	£ 9.17	£ 7.27	£ 6.49	£ 6.78	£ 8.53	£ 10.39

But there is every reason to believe that, for several years to come, Russian commercial policy will, so far as the existing treaties of commerce permit it, tend towards increased rather than relaxed protection, and in this anticipation foreign capitalists have, for some time, shown a growing inclination to establish factories in Russia. Here again, though there are many British traders, technical managers, and foremen in Russia, the German element predominates. Many years may elapse before Russia can become a leading manufacturing country, but her growth towards industrialism has recently been shown in a remarkable manner at the "All-Russian" Exhibition in Nijni-Novgorod.

This National Exhibition, the fifteenth of its kind, was patronised by the Russian Government and generally supported by the manufacturers. It has attracted little attention abroad, but Pharmacist L. J. Volpian, of St. Petersburg, gives an account of the chemical part of it in the *Pharm. Zeitschrift für Russland*, which reveals the extraordinary advance of Russian chemical industry. The imports of nitric and hydrochloric acid into Russia have fallen from 19,000 in 1885 to 313 tons in 1894; in other words, the empire is now practically independent of the foreigner for its supply of two of the principal bases of chemical industry. As for that still more important article, sulphuric acid, Russia makes all she requires. No fewer than 15 sulphuric acid factories were represented at Nijni-Novgorod. As with the acids, so it is with the closely-allied alkali industry. This branch of manufacture struck root in Russia all the quicker, because there were no old-

established interests with antiquated processes to be got rid of. The semi-foreign manufacturers who established the soda industry in Russia, the firm of Liabimov-Solvay, maintain two enormous factories in the Governments of Perm and Ekaterinoslav. Two years ago these works produced 45,406 out of the 61,450 tons of soda crystals consumed in the empire. Soda-ash and caustic soda industries have also been successfully established. The caustic soda works are mostly situated in the neighbourhood of Baku, where the product is used in the refining of petroleum derivatives, and where the abundance of raw material (Mirabolith) enables the makers to turn it out cheaply by the Leblanc process. Along with the sulphuric acid industry there has sprung up in Russia an important manufacture of chromate salts, vitriol, phosphates, lead, zinc, tin, strontium, and copper salts, mineral dyes, &c., all of which find employment in the textile, pottery, and other young industries. Platinum is almost a Russian monopoly, and no one will grudge Russia the new industry of the manufacture of platinum apparatus represented at her last National Exhibition.

In the manufacture of organic chemicals, and especially in that of pharmaceutical preparations, Russia is still dependent upon the foreigner for nine-tenths of her requirements, although the proportion grows less year by year. But since the All-Russian Exhibition of 1882, two refineries of boracic acid have been established. Chloroform, sulphuric ether, tannin, collodion, chloral hydrate, and tartrate of antimony are also made in the country, though not in sufficient quantity to cover the requirements. And tartaric acid making has been commenced. It is said that the argol from the Russian wine-growing districts serves for raw material, but the quality is confessedly poor, 10 per cent. of "tartaric acid"—or, say, about 13 per cent. of bitartrate of potash—being the average yield. We wonder that it pays for working.

In medicinal plant growing, the progress of Russia is very great. Six castor-oil factories, all working from Russian-grown seed, were represented at Nijni-Novgorod. Castor-seed growing, like other new agricultural pursuits, is assisted by the Government. An essential oil industry is also springing up, principally in the southern provinces. But, with few exceptions, it is carried on in a primitive fashion, and yields wretched products. Oils of peppermint,

wormwood, caraway, fennel, anise, and pine-needles are manufactured, but only the pine-needle oil is really good. The industry, however, faulty though it be, is making its influence felt upon the seed-market, for the exportation of essential oil seeds for distillation in Britain, Germany, and elsewhere has lately received a noticeable check.

Russian wool-fat and petroleum jelly are poor in quality. Benzine-distilling, on the other hand, is a flourishing business. This is not surprising in a country which, within the past 15 years, has developed the second largest petroleum industry in the world. From 31,500 galls. in 1882, the Russian benzine output had risen to nearly 1,570,000 galls. in 1894. The firm of Nobel owns 188 miles of petroleum pipe lines, and 1,157 tank-waggons for the conveyance of its products by rail.

The industry of the dry distillation of wood in Russia is only just beginning. In Northern Russia, away from the railways, there are still many thousands of square miles under wood, and a smaller area covers portions of the Caucasus. Yet up to the present only  $\frac{1}{2}$  per cent. of all the resin, and but a slightly larger proportion of the turpentine, used in Russia has been of Russian manufacture. It has generally been assumed that the Russian fir (*Pinus sylvestris*) could not be made to yield turpentine and rosin of equal quality or abundance to the French or American pines. The Russian Government gave Prof. Flazivski, of Kasan, a slice of Crown forest to experiment on, and he reports that Russian turpentine, if collected by the French process, does not differ, chemically or physically, from the French, except that it is dextro-rotatory to the same degree that the French is levo-rotatory. Moreover, the Professor has obtained a balsam from *Abies Sibirica* that will advantageously replace Canada balsam for technical and microscopic purposes. The day of the chemical exploitation of these forests is therefore dawning, and within a few years Russia may export, instead of buy from abroad, acetic acid, wood-naphtha, acetone, wood-vinegar, and acetate of lime.

The value of the output of chemicals of all kinds in Russia, according to the statistics of the Ministry of Trade and Industry (which need not be implicitly believed), was 15,437,000 r. in 1880, and 29,822,000 r. in 1890. The importation of chemical products into the country has declined from 19,262,000 r.'s worth in 1880 to 14,402,000 r.'s worth in 1890.

Bottles..... ..	680,650	775,986	324,901	370,845
Other kinds.... ..	224,836	242,258	170,758	190,450
Leather:—				
Unwrought ....	159,037	138,069	1,422,747	1,279,702
Wrought..... Value £	..	..	355,912	394,504
Seed oil..... Tons	49,154	58,293	990,311	1,088,374
Floorcloth..... Sq. Yds.	22,483,200	23,415,400	857,430	954,650
Painters' materials Val. £	..	..	1,556,579	1,657,808
Paper..... Cwt.	906,812	1,060,620	1,436,630	1,629,814
Rags..... Tons	49,259	52,977	293,821	286,883
Soap..... Cwt.	728,398	719,651	756,704	744,818
Total value .....	..	..	31,387,408	33,583,916

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

## I.—PLANT, APPARATUS, AND MACHINERY.

## APPLICATIONS.

28,691. G. Morriss. Improvements in muffles for annealing and like purposes. Dec. 15.

28,718. T. Hendaessy. Improvements in and relating to gas generators. Complete Specification. Dec. 15.

28,728. P. E. Placet. Improvements in the lining of crucibles and furnaces. Filed Dec. 15. Date applied for July 24, 1896, being date of application in France.

28,742. H. B. Wright. Improvements in mechanical water purifiers. Complete Specification. Dec. 15.

28,763. J. Y. Johnson.—From The Electric Rectifying and Refining Co. See Class XVII.

28,893. G. Nayler and A. Nayler. An improved fire retort. Dec. 16.

29,000. P. J. E. E. Chambost. Improvements in apparatus for heating or evaporating by means of hydrocarbon liquids of any density. Dec. 17.

29,318. W. Stagg, R. T. Glover, and J. G. Glover. Improvements in and connected with pressure or vacuum gauges. Dec. 21.

29,377. J. Hill. Improvements in filter presses. Dec. 22.

29,491. J. V. Forns. Improvements in tele-thermometers. Complete Specification. Dec. 22.

29,576. W. W. Hughes. Improvements in or relating to electric furnaces. Dec. 23.

29,587. E. Gauhe and Gockel. Improvements in mixing drums. Complete Specification. Dec. 23.

29,757. R. H. Yeomans. Improvements in furnaces for evaporating pans and other purposes. Dec. 24.

29,878. Starkey Bros., Ltd., and F. Hinchliffe. Improvements in the means or method for the consumption of smoke in furnaces. Dec. 29.

29,884. T. G. Webb. Improvements in and connected with apparatus for concentrating sulphuric acid and other liquids. Dec. 29.

1897.

38. S. A. Everett. Furnace for burning powdered fuel. Jan. 1.

81. W. Glover. Improvements in apparatus for heating air for drying purposes. Jan. 1.

154. S. Shail. An improved muffle furnace. Jan. 4.  
 189. W. L. Gilder. Improvements in or relating to furnaces. Complete Specification. Jan. 4.  
 446. T. Morton and W. S. McLennan. Improvements in washing apparatus. Jan. 7.  
 746. C. Gautier and N. Wehrle. Improvements in carburetted apparatus. Complete Specification. Jan. 11.  
 852. T. B. Lightfoot.—From The Gesellschaft für Linde's Eismaschinen. Apparatus for the production of ice and for cooling liquids by the expansion of compressed air. Complete Specification. Jan. 12.  
 853. T. B. Lightfoot.—From The Gesellschaft für Linde's Eismaschinen. Safety and regulating appliance for apparatus for compressing vapours of ammonia and other volatile liquids. Complete Specification. Jan. 12.  
 882. C. Guattari. An improved condenser. Jan. 12.  
 1138. H. H. Lake.—From P. H. Burrell and E. J. Burrell. Improvements in centrifugal liquid separators. Complete Specification. Jan. 15.

## COMPLETE SPECIFICATIONS ACCEPTED.\*

1895.

- 20,770. W. Busche. See Class IX.

1896.

424. G. E. Sherwin. Appliances for cooling and heating air and liquids. Jan. 13.  
 1228. D. M. Hawes. See Class XI.  
 2859. J. G. Lorrain. Apparatus for filtering and purifying liquids. Jan. 13.  
 4266. H. J. Fraser. Evaporative and other condensers, evaporators, and the like. Jan. 20.  
 6785. H. L. Doelton. Condensing worms constructed of pottery. Jan. 13.  
 11,345. A. Gates. Apparatus for mixing liquids. Dec. 23.  
 23,031. P. Funfak. Vessels for holding corrosive substances or the like. Jan. 13.

## II.—FUEL, GAS, AND LIGHT.

## APPLICATIONS.

- 28,518. J. Bland. Fuel cartridges. Dec. 14.  
 28,588. L. Mond. Improvements in or relating to the production of a mixture of air and water-vapour for gas producers. Dec. 14.  
 28,592. E. Bert. Improvements in the production of ozone. Dec. 15.  
 28,721. R. G. Leventhorpe. Improvements in the production of hydrogen gas and in apparatus therefor. Dec. 15.  
 28,722. H. R. Bean and H. Ringwood. Improvements in generators and holders for acetylene and other gases. Dec. 15.  
 28,776. A. G. Smith and A. J. Smith. A floating acetylene gas generator for the illumination of harbour works, floating buoys, ponds, rivers, or such like. Dec. 16.  
 28,853. W. P. Thompson.—From The Continental-Gas-Glühlicht-Actien-Gesellschaft "Meteor" vormals Kroll, Berger, and Co. Improvements in oil burners applicable for incandescent lighting. Dec. 16.  
 29,057. J. Edwards. Improved method of treating the mantles of incandescent gas burners to render them more retractory, the same being also applicable as a preservative of india rubber. Dec. 18.  
 29,168. E. Richard-Lagerie. Apparatus for producing acetylene gas. Dec. 19.  
 29,188. W. P. Thompson.—From L. L. H. Gerard. Improvements in or connected with apparatus for producing acetylene gas. Dec. 19.  
 29,202. D. Nagy. A new or improved process for making brown coal and lignite coke. Complete Specification. Dec. 19.  
 29,246. J. Cole and J. E. Zealey. Improvements in and connected with the burning of oils for illuminating and heating purposes. Dec. 21.  
 29,301. P. de Resener and H. Luchaire. An improved process for the manufacture and purification of acetylene. Filed Dec. 21. Date applied for Aug. 21, 1896, being date of application in France.  
 29,320. P. de Resener and H. Luchaire. Improvements in apparatus for the manufacture of acetylene. Filed Dec. 21. Date applied for Aug. 21, 1896, being date of application in France.  
 29,422. P. Cannell-Bunn. Improved mantles for gas and other burners. Dec. 22.  
 29,435. D. Pemberton and J. Lewis. Improvements in acetylene and other gas generators. Dec. 22.  
 29,495. C. Guattari. Improvements in acetylene gas generating apparatus. Dec. 22.  
 29,500. E. Quelle. Improvements in apparatus for generating acetylene gas. Complete Specification. Dec. 22.  
 29,554. H. K. Spence, A. Beveridge, W. G. Beveridge, and S. M. Beveridge. Improvements in acetylene gas generators. Dec. 23.  
 29,596. J. O. O'Brien.—From P. P. H. Mace. Improvements in feed governors for apparatus for producing acetylene gas. Dec. 23.  
 29,597. A. Bandsept. Improvements in incandescent burners. Dec. 23.  
 29,603. J. Spurge. Improvements in gas-cleansing apparatus. Dec. 23.  
 29,613. A. Rommoser and A. von Hake. Improvements in and relating to incandescent lights. Complete Specification. Dec. 23.  
 29,736. C. Colas. Improvements in means for incandescent lighting. Complete Specification. Dec. 24.  
 29,750. G. Claude and A. Hess. An improved method of storing acetylene for lighting and other purposes. Dec. 24. Date applied for June 6, being date of application in France.  
 29,768. W. H. Dargue. An improved apparatus for the production, drying, purifying, and storage of acetylene gas. Dec. 28.  
 29,780. A. Dorst. A new incandescent light. Dec. 28.  
 29,832. P. de Resener and H. Luchaire. Improvements relating to burners for use with acetylene. Dec. 28. Date applied for June 30, 1896, being date of application in France.  
 29,858. F. Altmann. Improved method and apparatus for burning liquid fuel. Complete Specification. Dec. 28.  
 29,863. C. Dellwik. Improvements in the production of water-gas and in apparatus therefor. Complete Specification. Dec. 28.  
 29,966. J. Y. Johnson.—From The Electric Rectifying and Refining Co. Improvements in and apparatus for producing ozone. Complete Specification. Dec. 29.  
 29,991. J. H. Dunn. Improvements in the generation of gas by means of electricity from coal, oil, or other carboniferous matter. Dec. 30.  
 30,037. P. de Resener. An improved apparatus for manufacturing acetylene. Dec. 30.  
 30,134. J. Schumacher. Improvements in apparatus for use in generating gas. Complete Specification. Dec. 31.

1897.

6. T. J. Meek, H. Davison, and J. Southam. An improvement in ascension pipes used in the manufacture of coal-gas. Jan. 1.  
 139. F. Trendel and J. Mücke. Process and apparatus for producing acetylene gas. Complete Specification. Jan. 2.  
 160. W. J. Holme. The lime-light incandescent mantle. Jan. 4.  
 187. G. Oppenheimer. Improvements in mantles for use in incandescent lighting. Jan. 4.  
 262. W. M. Ward. See Class XVIII. B.

\* See Note (\*) on previous page.

294. O. Kern. Improvements in incandescent gas burners. Jan. 5.

298. G. Hervieu and L. Macke. Improvements in apparatus for generating acetylene and other similar gases. Jan. 5.

328. J. Zimmermann. Improvements in processes of and apparatus for forming and burning acetylene and similar gases. Complete Specification. Jan. 5.

330. D. W. Sugg. Improvements in and relating to incandescent gas burners. Jan. 5.

409. A. A. Humphrey. Improvements in the method of and apparatus for burning liquid fuel. Jan. 6.

501. R. Langhans. Improvements in the manufacture of incandescing media for use in incandescent gas lighting. Jan. 7.

512. G. Lebrun and F. Cornaille. Apparatus for producing acetylene gas. Filed Jan. 7. Date applied for June 17, 1896, being date of application in France.

658. L. Tâdé. Improved apparatus for the production of acetylene. Jan. 9.

885. T. Holliday. Improvements in means or apparatus for use in the production, storing, and application of acetylene gas. Complete Specification. Jan. 12.

911. V. Daix. Improvements in or relating to the production of acetylene gas. Complete Specification. Jan. 13.

955. G. Grossard and E. Psychiers. Apparatus for the production of acetylene gas. Jan. 13.

1153. E. H. F. des Essards. An improved generator for acetylene and certain other gases. Complete Specification. Jan. 15.

1194. H. Simon. Improvement in by-product coke ovens. Jan. 16.

1240. F. E. Ross and A. J. Gibson. Improvement in apparatus for the production of combustible gas from towns' refuse and sewage sludge. Jan. 16.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

317. G. Love. Apparatus applicable to coke ovens. Jan. 6.

682. H. C. B. Forester. Manufacture of artificial fuel. Jan. 20.

841. G. W. Brefit and F. G. Treharne. A new furnace for producing coke, with or without suitable apparatus for collecting the by-products. Jan. 20.

858. A. Devis. Process and apparatus for carburizing air. Jan. 20.

873. W. Raydt. Obtaining carbonic acid from gaseous mixtures. Jan. 20.

1332. C. G. Luis. Apparatus for use in the production of acetylene gas. Jan. 13.

1576. L. Denayrouze. Incandescent lighting with an intimate mixture of gas and air. Dec. 23.

1681. W. H. Wheatley.—From F. Woernle. Manufacture of incandescence bodies for illuminating purposes. Dec. 31.

1682. W. H. Wheatley.—From C. Schmid. Manufacture of incandescence bodies for illuminating purposes. Dec. 31.

3219. E. B. Pym and J. Gore. Apparatus for use in the manufacture of acetylene gas. Jan. 13.

3324. C. M. Schnauder. Manufacture of fuel blocks. Jan. 13.

3681. W. Mackean and the Incandescent Gas Light Company, Ltd. Manufacture of mantles for incandescent gas lighting. Dec. 23.

4000. W. Nicholls. Manufacture of incandescence bodies for illuminating purposes. Dec. 31.

4285. J. R. Wigham. A method of burning acetylene gas or other very rich hydrocarbon gas. Jan. 13.

5916. F. A. MacKinnon. A new or improved method or process for the treatment of coke so as to render it suitable for transport. Jan. 6.

21,098. S. Katz. Manufacture of charcoal fuel blocks. Jan. 20.

22,646. A. G. Smith. Acetylene gas generator, purifier, and holder. Jan. 13.

22,647. A. J. Smith and A. G. Smith. A method of adapting acetylene gas for use on cycles, carriages, or other vehicles. Jan. 20.

23,154. F. G. Bartlett. Burners for incandescent gas-lighting. Jan. 13.

23,595. E. Theisen. Purifying gases or vapours and gaining by-products therefrom, and in subjecting gases or vapours to the action of solid or liquid substances, and the converse by means of centrifugal action, and apparatus therefor. Jan. 13.

24,274. R. Turr. Apparatus for the production and combustion of acetylene gas. Jan. 20.

27,085. S. D. Gillet, G. Forest, and J. E. O. Bocande. A new or improved arrangement of apparatus for lighting by acetylene gas. Jan. 13.

#### IV.—COLOURING MATTERS AND DYES.

##### APPLICATIONS.

28,557. W. H. Claus and A. Ree. Manufacture of brown colouring matters containing sulphur. Dec. 14.

28,810. W. E. Heyes.—From The Chemical Works, Sandoz. Production of substantive trisazo colouring matters. Complete Specification. Dec. 16.

29,706. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of dyestuffs of the series known as patent blue. Dec. 24.

29,717. G. B. Ellis.—From La Société Chimique des Usines du Rhone, anciennement G. P. Monnet et Cartier. Improvements in the manufacture of chlorine derivatives of toluene. Dec. 24.

29,827. P. A. Newton.—From The Farbenfabriken vormals F. Bayer and Co. Improvements in the production of dyestuffs on fibre. Dec. 28.

29,828. S. Pitt.—From L. Cassella and Co. Production of a brown colouring matter. Dec. 28.

30,015. W. E. Heyes.—From The Chemical Works, Sandoz. Production of violet and blue colouring matters of the triphenylmethane group. Complete Specification. Dec. 30.

1897.

304. R. W. James.—From W. J. Matheson and Co., Ltd. Process for the manufacture of aceto-derivatives of the simpler aromatic amines. Complete Specification. Jan. 5.

765. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Improvements in the manufacture of colouring matters and of new intermediate products. Jan. 11.

1145. H. Imray.—From F. Peterson and Co. Manufacture of new colouring matters from benzidin sulpho-acids. Complete Specification. Jan. 15.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

2946. Levinstein, Ltd., and I. Levinstein. Production of new sulpho-acid and of colours derived therefrom. Jan. 6.

2999. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of sulphonic acids of the meta-amidophenolphthaleines and their alkyl derivatives. Jan. 13.

3966. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of new phthaleine colouring matter. Jan. 6.

5068. T. R. Shillito.—From J. R. Geigy and Co. Manufacture of greenish-blue colouring matters or dyes of the malachite green series. Dec. 31.

5090. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of safranin azo dyestuffs soluble in water. Jan. 13.

5128. O. Imray.—From The Society of Chemical Industry in Basle. Manufacture of new colouring matters dyeing from blue-green to blue, and of new chloro-derivatives and sulphonic derivatives of benzoic aldehyde therefor. Dec. 31.

## V.—TEXTILES, COTTON, WOOL, SILK, ETC.

## APPLICATIONS.

28,613. D. M. Sutherland and W. McLaren. Improvements in treating nitro-cellulose for the purpose of coating or impregnating textile and other fabrics. Dec. 14.

28,870. O. Seyfert. A process for giving a silk appearance to cotton. Dec. 16.

29,832. O. Inray. — From The Farbwerke vormals Meister, Lucius, and Brüning. See Class VI.

1897.

90. H. W. Godfrey. Improvements in the manufacture of floorcloth and the like. Jan. 1.

198. F. Walton. Improvements in apparatus for manufacturing mosaic floorcloth. Complete Specification. Jan. 4.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

1104. J. L. Bottomley. Manufacture of yarn. Jan. 13.

3517. J. R. Hoyle and H. Colburn. Back-washing machines for use in the treatment of wool or other fibrous substances. Jan. 13.

8235. J. Weiss. A chemical process for the production of white or coloured crape-like designs on cotton, linen, or other fabrics or yarns of vegetable origin. Jan. 20.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

## APPLICATIONS.

28,552. W. Hadfield, J. J. Sumner, and H. Hadfield. Improvements in apparatus for washing and treating woven goods in the piece. Dec. 14.

28,553. W. Hadfield, J. J. Sumner, and H. Hadfield. Improvements in apparatus for use in the continuous bleaching and washing of woven goods in the piece, applicable also in the washing and clearing of printed or dyed goods. Dec. 14.

28,840. A. J. Huston and E. Ramsden. Improvements in or connected with apparatus for the settling and filtration of suds, dye water, sewage, and the like, and obtaining useful products therefrom. Dec. 16.

28,984. J. C. Hamer and J. Haslam. Improvements in or connected with the dyeing of aniline black. Dec. 17.

29,150. F. A. Gatty and Co., Ltd., and V. H. Gatty. Improvements in dyeing wool or other animal fibres in either the raw or manufactured state. Dec. 19.

29,154. T. Russell. Improvements in and relating to the printing of calico and like wet fabrics. Dec. 19.

29,645. W. Hadfield, J. J. Sumner, and H. Hadfield. Improvements in apparatus for use in the continuous bleaching and washing of woven goods in the piece, applicable also in the washing and clearing of printed or dyed goods. Dec. 24.

29,832. O. Inray. — From The Farbwerke vormals Meister, Lucius, and Brüning. Production of local durable silk-like gloss-effects on cotton or linen stuffs by means of printing. Dec. 28.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

1407. J. Y. Johnson. — From E. G. May, Sohne, and Co. Improvements in the production of coloured figures or designs and ornamental effects. Dec. 9.

2840. T. Halliwell and J. Stones. Apparatus for dyeing, bleaching, or scouring fibrous materials. Jan. 13.

5712. J. Barnes. The production of fast colours on animal fibre by the aid of oxide of titanium. Jan. 20.

26,495. A. Vogelsang. Process for treating dry materials (more particularly fibrous substances) with liquid. Dec. 31.

## VII.—ACIDS, ALKALIS, AND SALTS.

## APPLICATIONS.

28,891. G. Kynoch and Co., Ltd., and A. T. Cocking. Improvements in purifying and concentrating sulphuric acid, in part applicable to the manufacture of nitric acid. Dec. 16.

29,066. E. J. Hunt and E. F. Watson. Improvements in the manufacture of chlorine. Dec. 18.

29,455. H. H. Lake. — From C. Pieper. A method of and apparatus for the continuous manufacture of ammonia from nitrogenous materials. Dec. 22.

29,884. T. G. Webb. See Class I.

29,922. J. D. Gilmour. Method of drying alkaline cyanides. Dec. 29.

1897.

28. E. J. Ball. Improvements in the treatment of substances containing potassium. Jan. 1.

204. G. Cipri. Improvements in the manufacture of sulphuric acid. Jan. 4.

381. A. K. McCosh. See Class X.

422. A. James. Improvements in the treatment of seaweed and the like for the production of iodine and other useful products. Jan. 6.

591. P. J. Worsley and The United Alkali Co., Ltd. Improvements in the manufacture of caustic soda or caustic potash from carbonate of soda or carbonate of potash. Jan. 8.

1248. H. H. Lake. — From J. S. Levi and Co. An improved process for obtaining barium carbonate from native sulphate of barium. Jan. 16.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

928. J. Foster. Improvements in and relating to the discharging of salts and the like from evaporators. Dec. 23.

3869. J. T. Conray, F. Hunter, and J. Brock. Manufacture of ferrocyanides from sulphocyanides. Dec. 23.

4743. L. G. Paul. Manufacture of nitrites of soda and potash. Jan. 6.

25,100. A. Schmidt. Process for purifying crude acetic acid. Jan. 20.

## VIII.—GLASS, POTTERY, AND ENAMELS.

## APPLICATIONS.

28,789. C. F. Ravenhill. Improved glaze for clay tobacco pipes. Dec. 16.

29,315. J. P. Guy. Improvements in or relating to machines for pressing and forming saggars or other earthenware articles. Dec. 22.

29,316. J. P. Guy. Improvements in hollow earthenware vessels, such as potters' saggars. Dec. 21.

29,386. R. F. Copeland. Improved construction of ovens for use in firing pottery-ware. Dec. 22.

29,589. F. Joynson, W. Harrison, and G. T. Joynson. Improved machine for the manufacture of glass bottles, jars, and the like. Complete Specification. Dec. 23.

29,844. P. Rataud. Process for the decoration of china, earthenware, glass, and the like by means of chromotography and photochromy. Dec. 28.

1897.

334. G. G. M. Hardingham. — From G. W. Blair. An improvement in the manufacture of glass articles. Complete Specification. Jan. 5.

## COMPLETE SPECIFICATION ACCEPTED.

1896.

1834. J. Jacques and W. E. McCalla. A new or improved manufacture of articles in glass, tile, pottery, metals, and like substances by a process for producing thereon letters, figures, or designs in permanent colours. Jan. 13.

# IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

## APPLICATIONS.

29,109. W. H. Coward. Improvements in the manufacture of composition and other compressed blocks for paving. Dec. 18.

29,212. Petrifite, Ltd.—From J. Steiger. An improvement in the manufacture of cement. Dec. 19.

29,654. O. Kraner. Process for the production of a material for making floors, plasterings, ceilings, walls, roofs, and the like without joints or chinks. Complete Specification. Dec. 24.

28,864. A. Zboril and A. Schenk. Improved plates, slabs, or the like for floors, pavements, fireplaces, and similar purposes, and method of manufacturing the same. Dec. 28.

30,117. A. Gutensohn. Improvement in the manufacture of fire-proof materials. Dec. 31.

1897.

322. A. Calladine. A new or improved cement. Jan. 5.

## COMPLETE SPECIFICATIONS ACCEPTED

1895.

20,770. W. Busche. Brick-burning and other kilns. Jan. 13.

1896.

2223. F. Turner. Manufacture of cement or artificial stone. Jan. 6.

3993. W. F. Williams. Artificial stone for building purposes. Jan. 20.

23,105. J. A. Just. Manufacture of compositions for paving and like purposes. Jan. 13.

24,242. A. Clery. Manufacture of artificial stone. Jan. 6.

24,902. A. Gries. Production of slabs or such like for building and other purposes. Dec. 23.

# X.—METALLURGY, MINING, Etc.

## APPLICATIONS.

28,714. J. B. Torres. Improvements in or relating to the extraction of gold, silver, and other metals from ores and the like. Dec. 15.

28,727. P. E. Placet. Improvements in the purification of aluminium and apparatus therefor. Dec. 15. Date applied for July 24, 1896, being date of application in France.

28,836. J. W. Spencer. Improvements in the manufacture of steel. Dec. 16.

28,880. C. de E. Llatas. Improvements in the manufacture of steel. Dec. 16.

29,080. J. W. Spencer. Improvements in the manufacture of steel in regenerative furnaces and the apparatus connected therewith. Dec. 18.

29,090. T. T. Sill. Improvements in the manufacture of red oxide from the waste liquors from galvanising works, tin-plate works, wet copper process, or other residual liquors containing iron in the form of chloride. Dec. 18.

29,251. R. D. Burnie and W. T. Lougher. An improved process for covering or coating steel and iron with copper or alloy of copper. Dec. 21.

29,284. J. B. Torres. Improvements in extracting gold, silver, and other metals from ores and the like, and in the apparatus therefor. Dec. 21.

29,317. P. E. Serrant, A. E. Ragetly, and F. G. H. Marville. An improved process of extracting gold from auriferous ores and tailings or residues. Dec. 21.

29,388. C. Wilcox and B. J. Hammersley. Certain improvements in annealing muffles for annealing cold-drawn steel and other metal tubes, metal sheets, and other metal articles. Dec. 22.

29,709. W. Kirkham. Improvements in crucible melting furnaces. Dec. 24.

29,795. C. W. Robinson. A new tool steel and means for producing the same. Dec. 28.

29,833. J. B. Clive. A new or improved appliance or apparatus to be used in the casting of metals and metallic alloys. Dec. 28.

29,846. S. Danner. Improvements in the manufacture of crucible steel. Dec. 28.

30,022. H. R. Angel. Improvements in the reduction of zinc blend and other ores. Dec. 30.

30,077. J. Burgess and W. A. Brodie. Improvements for use in producing castings in malleable iron, mild steel and other metals. Dec. 31.

30,141. A. F. Cotillas. An improved process of casting for reducing the density of cast articles. Complete Specification. Dec. 31.

30,152. A. M. Clark.—From R. H. T. Biewend and The Actien Gesellschaft für Zinc Industrie vormals W. Grillo. Process of recovering zinc from zinciferous gases in the distillation and smelting of zinc. Dec. 31.

1896.

91. J. D. Grey and T. Gwynne. Improvements in the treatment of sheet iron and steel in the manufacture of polished sheets. Complete Specification. Jan. 1.

290. W. E. May. Improvements relating to the casting of metals and to apparatus for use in connection therewith. Jan. 5.

292. H. R. Angel. Improvements in the reduction of zinc blend refractory ores, and recovery of the lead and precious metals therefrom. Jan. 5.

381. A. K. McCosh. Improvements in obtaining cyanides and other products from blast furnaces. Jan. 6.

513. W. S. Simpson. Improved means for effecting close or different texture of metallic particles or molecules during the process of casting. Jan. 7.

516. A. S. F. Robinson. Improved method and machinery or apparatus for extracting gold or other valuable metal from crushed ore or material containing it. Jan. 7.

531. S. Shaw. Improvements in the recovery of zinc or spelter from alloys or waste materials containing metallic zinc. Jan. 8.

560. S. Shaw. Improvements in the treatment of argentiferous lead. Jan. 8.

662. H. R. Angel. Improvements in the reduction of zinc blend and other ores and recovery of the lead and other metals therefrom. Jan. 9.

880. A. Etard. Improvement in the treatment of ores or other matters containing gold, silver, or copper, for the obtaining of the metal therefrom. Jan. 12.

918. G. A. Webb and W. A. Thoms. An improvement in alloys. Jan. 13.

990. G. F. Redfern.—From J. L. Gauharou. Improvements in the treatment of metals and alloys. Jan. 13.

1034. H. R. Angel. Improvements in the reduction of zinc blend and other ores, and recovery of the lead with other metals therefrom. Jan. 14.

1062. C. T. J. Vantin. An improved process for the reduction of argentiferous or non-argentiferous complex sulphide ores of lead and zinc. Jan. 14.

## COMPLETE SPECIFICATIONS ACCEPTED.

1895.

23,152. E. J. Post. Process and apparatus for plating articles or covering the same with metal. Jan. 13.

24,703. R. Heathfield and W. S. Rawson. An improvement in galvanising. Dec. 23.

1896.

203. E. Placet. Treatment of iron and steel. Dec. 31.

303. C. C. Longridge and G. T. Holloway. Improvements in plant and process for smelting auriferous antimony ores. Jan. 6.

1055. A. J. Bonlt.—From C. Prioux and C. Hugot. Soldering metals. Jan. 20.

1316. A. J. Boulton.—From C. J. L. Otto. Manufacture of iron and steel. Jan. 13.

1970. R. B. Boulton. The application of inlaying of metal or alloy or amalgams, when in a softened condition, in or upon any hard substance devoid of life, and which has been formed into any pattern, lines, letters, or designs. Jan. 20.

2327. T. M. Ash and H. N. Weldon. An improved process for plating or coating non-metallic articles with metals. Jan. 20.

18276. H. H. Lake.—From H. Schweitzer and E. E. Lungwitz. Production of steel and the refining of iron ore. Dec. 31.

23,954. J. Y. Johnson.—From J. J. Deeble. Apparatus for use in the extraction of gold from auriferous material by the aid of chemical solvents. Dec. 31.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### APPLICATIONS.

28,723. J. Schull. Improvement in secondary batteries for electricity. Dec. 15.

28,764. F. Hunter and the United Alkali Co., Ltd. Improvements in apparatus for use in electrolysis, more especially intended for use in the electrolysis of zinc chloride. Dec. 15.

29,115. F. King. Improvements in electric storage or secondary batteries. Dec. 18.

29,306. A. Heil. Improvements in secondary batteries. Complete Specification. Dec. 21.

29,307. A. Heil. Improvements in peroxide of manganese and carbon electrodes, and in the method of producing the same. Complete Specification. Dec. 21.

29,362. W. H. Akester and M. Miroy. An improvement in accumulators. Dec. 22.

29,363. W. H. Akester and M. Miroy. Improvements in or relating to accumulators. Dec. 22.

29,571. C. D. Abel.—From C. N. Seidneff. A new galvanic element and exciting and depolarising liquids therefor. Complete Specification. Dec. 23.

29,907. C. Brault. Improvements in the manufacture and production of elements or plates for electrical storage batteries. Complete Specification. Dec. 29.

29,981. A. W. Turner and A. Hiorns, jun. Improvements in and relating to electric accumulators. Dec. 30.

30,024. F. Wente. Improved composition of filling material for electrolytical and galvanic purposes. Dec. 30.

1897.

251. G. W. Harris and R. J. Holland. Improvements in secondary batteries and process of forming same. Complete Specification. Jan. 5.

423. D. G. Fitzgerald. Improvements in primary and secondary voltaic batteries. Jan. 6.

425. F. King. Improvements in or connected with secondary batteries. Jan. 6.

490. W. Wright. Improvements relating to the electric deposition of metal on pipes, tubes, and other articles. Jan. 7.

495. A. Koch. Improvements in apparatus for the electrolytic treatment of alkaline salts. Jan. 7.

615. E. Bohn. Improvements in and applicable to means for electrically obtaining ozone, and employing the same for curative and other purposes. Jan. 9.

631. W. P. Freeman. Improvements in primary batteries. Complete Specification. Jan. 9.

652. D. W. R. E. Thomson and H. C. Bull. Improvements in or connected with primary electric batteries. Jan. 9.

859. A. Schermann. Process for the extraction of metallic alloys and pure metals by electric heat. Complete Specification. Jan. 12.

995. W. S. Doe. Improvements in galvanic batteries. Jan. 13.

996. W. Majert. Improvements in and relating to accumulator plates. Jan. 13.

1026. J. E. Hartley.—From F. W. Zingsen. Improvements in apparatus for the electro-deposition of metals. Jan. 14.

1038. W. H. Graham. Process and apparatus for electro-thermally treating materials. Jan. 14.

1099. W. Rowbotham. Improvements in and relating to accumulators or storage batteries. Jan. 15.

1203. H. W. Hancock and A. H. Dykes. An improved secondary battery plate. Jan. 16.

1204. H. W. Hancock and A. H. Dykes. An improved method of preparing positive plates for secondary batteries. Jan. 16.

### COMPLETE SPECIFICATIONS ACCEPTED.

1895.

25,002. R. Heathfield and W. S. Rawson. Electrolytical apparatus. Dec. 31.

1896.

535. H. W. Headland. Primary and secondary batteries. Jan. 6.

773. H. W. Headland. Secondary batteries. Jan. 13.

842. S. O. Cowper-Coles. Manufacture of electric conductors. Dec. 31.

1069. C. Pollak. Electrical condensers. Jan. 20.

1228. D. M. Hawes. Manufacture of battery cells or vessels to contain acids or other chemicals. Jan. 20.

1669. W. Turner. Electric batteries. Jan. 13.

13,520. C. Pollak. Plates for accumulators or secondary batteries. Jan. 20.

16,268. W. Rowbotham. Electric batteries. Jan. 13.

26,281. K. Klic. Manufacture of metal sheets or strips by electro-deposition. Jan. 6.

## XII.—FATS, OILS, AND SOAP.

### APPLICATIONS.

28,682. J. L. Garle and C. C. Frye. A new or improved process for the decolorisation of palm oil. Dec. 15.

28,781. H. A. Wild. An improved laundry-cream composition. Dec. 16.

1897.

112. Read, Holliday, and Sons, Ltd., and T. Holliday. Improvements in the manufacture of soap. Jan. 2.

123. G. Rezek. An improved washing material and process for making the same. Complete Specification. Jan. 2.

751. J. T. Potts. Improvements in the manufacture of soap. Jan. 11.

1067. J. Mendess. Improvements in compounds for cleansing and dyeing purposes. Jan. 14.

1208. W. P. Thompson.—From J. Van de Bücken and S. Gattfeld. Improved soap for carpets. Complete Specification. Jan. 16.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

3329. G. D. Macdonald and The Lendon and Dundee Syndicate, Ltd. Improved means and apparatus connected with and for the marking of soap tablets, cakes, or bars with indelible colour. Jan. 6.

24,909. G. W. Hansen. Manufacture of waterproof dubbing for leather and leather goods. Dec. 23.

## XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

### APPLICATIONS.

28,598. L. Greening. Improvements in the manufacture of material suitable for use as a substitute for india-rubber, gutta-percha, ivory, horn, vulcanite, and the like; also for waterproofing paper, leather, and other fabrics; and as a varnish. Dec. 14.

28,698. H. Sutton. Imitation stained glass enamel. Dec. 15.

28,950. F. Beindorff. A process for making colours for water-colour painting. Complete Specification. Dec. 17.

29,805. F. Eilershausen. Improved method of preparing rubber substitute. Dec. 28.

30,047. P. A. Duprez. Process and apparatus for de-vulcanising or desulphurising vulcanised caoutchouc waste. Dec. 30.

1897.

1049. P. H. King, V. M. H. Beever, and C. T. Sidgwick. Manufacture of synthetic caoutchouc and analogous compounds. Jan. 14.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

2568. J. L. Pollock. Improvements in air- and water-proofing varnishes or compositions. Dec. 23.

3906. W. Hampe and C. Schuabel. Manufacture of zinc oxide. Jan. 6.

26,015. A. Schmidt. Process for obtaining turpentine from wood and wood waste. Jan. 13.

28,283. W. A. Hall. Water-paints. Jan. 20.

#### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

##### APPLICATIONS.

29,885. W. E. Heys.—From G. Wendler. Improvements in and relating to tannaceous and resinous solutions and mixtures for sizing and finishing textile fabrics, paper, and the like. Dec. 29.

1897.

655. E. S. Cook. Improved method of preparing raw hides and the manufacture of travelling trunks, portmanteaus, and the like therefrom. Jan. 9.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

1587. M. Hocquet. The manufacture of new compounds or composition from cork and other materials for use as substitutes for wood, leather, and other substances, or for other purposes to which same may be applicable. Jan. 20.

2572. H. L. J. Roy. Process and apparatus for the rapid tanning of hides, applicable also for dyeing and otherwise treating leather. Dec. 31.

16,764. J. Blunck. Process of tanning hides, skins, or the like. Jan. 6.

#### XVI.—SUGARS, STARCHES, GUMS, ETC

##### APPLICATIONS.

29,319. J. Brown and W. J. Brown. Improvement in the manufacture of artificial gum. Dec. 21.

1897.

24. E. L. Newsome. Improved appliance for supplying glucose, syrup, or other material to preserving pans when boiling. Jan. 1.

586. R. Ansgore. An improved starch preparation and process of making the same. Complete Specification. Jan. 8.

742. H. W. Mellon and R. G. Whitford. Improvements in vegetable syrups. Jan. 11.

1141. A. Classen. Manufacture of chemical compounds of starch and dextrine or equivalent bodies with formaldehyde or its equivalents. Jan. 15.

1155. A. Collette, jun., and A. Koidin. A process for utilising moulds or microscopie fungi for extracting from residues, particularly those arising from the treatment of amylaceous and sugary substances, alcohol, and mucidines capable of being used in panification, distillation, saccharification, and the like. Jan. 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

1960. E. Shaw. Boiling sugar and other syrups. Jan. 20.

4560. D. N. Bertram. Strainers for treating paper pulp, separating fibrous materials from starch, and like purposes. Jan. 13.

6508. W. Feld. Process for the extraction of sugar from molasses and other saccharine liquors by means of barium hydroxysulphide, and the regeneration of the latter from the by-products produced. Jan. 13.

24,038. F. W. Golby.—From J. Hensel. See Class XVIII. A.

#### XVII.—BREWING, WINES, SPIRITS, ETC.

##### APPLICATIONS.

28,713. C. Killing. Process and apparatus for purifying crude alcohol and other alcoholic mixtures. Complete Specification. Dec. 15.

28,763. J. Y. Johnson.—From The Electric Rectifying and Refining Co. Improvements in and apparatus for purifying and decolorising saccharine solutions and other liquids. Complete Specification. Dec. 15.

29,965. J. Y. Johnson.—From The Electric Rectifying and Refining Co. Improvements in and apparatus for treating or purifying, rectifying, ageing, deodorising, and decolorising alcoholic and other liquids or liquified matter. Complete Specification. Dec. 29.

1897.

275. J. Jacquemin, W. A. Ouston, and G. H. Newman. An improvement in the production of pure alcohol by the fermentation and distillation of dried fruit. Jan. 5.

284. J. W. L. Hepton, A. E. L. Hepton, and T. Clarke. Improvements in unions applicable for spargers and other purposes. Jan. 5.

978. H. Muller-Thurgau. Process for the production of non-alcoholic or feebly alcoholic fruit juices (fruit and grape wines) which may be kept or preserved without change. Jan. 13.

1162. F. C. Haeck. A new or improved process and apparatus for rapidly and economically ageing or maturing alcoholic beverages. Complete Specification. Jan. 15.

#### COMPLETE SPECIFICATION ACCEPTED.

1896.

24,058. F. W. Golby.—From J. Hensel. Process for the production of a food of a high nutritive value from the molasses of raw beet-sugar. Jan. 20.

#### XVIII.—FOODS, SANITATION, ETC., AND DISINFECTANTS.

##### APPLICATIONS.

##### A.—Foods.

28,708. A. J. C. Rayson. The manufacture of a substitute for coffee. Complete Specification. Dec. 15.

1897.

899. J. J. Hazard. Improvements in the preservation of organic matters and in apparatus for use in connection therewith. Jan. 12.

##### B.—Sanitation.

28,840. A. J. Inston and E. Ramsden. See Class VI.

29,918. A. P. I. Cotterell. An appliance for facilitating the deposition or precipitation of sewage in sewage tanks, applicable also to clarifying water and other liquids. Dec. 17.

29,009. J. F. G. de Bonardi (Marquis du Menil). Method and furnace for the incineration of so-called garbage and the recovery of ammonia therefrom. Dec. 17.

29,223. I. S. McDougall. Improvements in the methods of, and apparatus for water purification. Complete Specification. Dec. 19.

1897.

107. W. Bagshaw. Improvements in filters and clarifiers for the treatment and purification of water, sewage, waste liquids, and the like. Jan. 2.

262. W. M. Ward. Improvements in the mode, means, and apparatus for treating smoke for the extraction of the carbon and other residual products resulting from imperfect combustion. Jan. 5.

654. W. M. Ducat. Improvement in the method of, and apparatus for purifying water sewage and other foul liquids. Jan. 9.

### C.—Disinfectants.

29,288. W. B. Bottomley. Improvements in and relating to material for use in the treatment and purification of sewage and other impure waters. Dec. 21.

29,484. J. Startin. Improvements in or relating to disinfectants, anti-septics, and the like. Dec. 22.

29,591. J. Hardwick. Improvements in deodorising, disinfecting, and anti-septic compounds. Dec. 23.

### COMPLETE SPECIFICATIONS ACCEPTED.

#### A.—Foods.

1896.

3260. T. Hyatt. Alimentary substances, their manufacture, and putting up or conditioning them for domestic use. Jan. 6.

3833. J. Dunn and W. Dunn. Treating lentils, peas, and other leguminous vegetables to obtain new alimentary products. Dec. 31.

26,498. W. F. E. Casse. Casse freezing process for preserving milk and cream. Jan. 13.

26,635. P. M. Justice.—From M. W. Marsden. An improved product obtained from corn or maize stalks, and a process of, and apparatus for making the same. Jan. 20.

#### B.—Sanitation.

821. J. H. Williams. Apparatus and process for purification, softening, or hardening of water for domestic, manufacturing, or other purposes. Dec. 23.

1038. R. E. von Lengerke. Filtration of sewage. Jan. 20.

### XIX.—PAPER, PASTEBOARD, Etc.

#### APPLICATIONS.

29,466. C. Deselle. A process for the manufacture of artificial ivory articles. Dec. 22.

29,829. C. D. Abel.—From Farbwerke Friedrichsfeld, P. Remy. Manufacture of waterproof paper and similar fabrics, and the production of compounds therefor. Dec. 28.

### COMPLETE SPECIFICATIONS ACCEPTED.

1895.

23,598. C. Brodbeck. Manufacture of fabrics from chemical cellulose. Jan. 20.

1896.

4560. D. N. Bertram. See Class XVI.

4713. C. F. Cross. Manufacture of alkali cellulose. Jan. 13.

6389. M. E. Asselot. Manufacture of celluloid. Dec. 23.

### XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

#### APPLICATIONS.

28,968. L. Lederer. A new or improved process for manufacturing *oxyphenoxacetic acids*. Complete Specification. Dec. 17.

28,969. L. Lederer. A process for the preparation of acetyl and laetyl derivatives of aniline and phenitidine. Complete Specification. Dec. 17.

29,322. J. Rosenberg. An improved process of producing tri-bromsalol. Dec. 21.

29,446. O. Imray.—From F. Hoffmann-La Roche and Co. Production of certain organic therapeutic preparations. Dec. 22.

29,447. O. Imray.—From F. Hoffmann-La Roche and Co. Manufacture of pure acetosulphanilate salts. Dec. 22.

1897.

445. R. Mackill. Improvements in obtaining nicotine from tobacco. Jan. 7.

656. J. Y. Johnson.—From C. F. Boehringer and Soehne. Improvements in the preparation of alkylated uric acids. Jan. 9.

1075. A. J. Boulton. From F. Fritzsche and Co. Improved process for production of iso-eugenol from oil of cloves, with the simultaneous extraction of terpene. Jan. 14.

1164. W. L. Wise.—From The Chemische Fab. von Heyden Gesellschaft mit beschränkter Haftung. Improvements in the manufacture of *o*-sulphamin benzoic acid alkylesters and of anhydro-*o*-sulphamin benzoic acid. Jan. 15.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

3706. J. Y. Johnson.—From The Vereinigte Chininfabriken Zimmer and Co. Manufacture and production of a pharmaceutical product. Dec. 23.

3791. G. B. Ellis.—From La Société Chimique des Usines du Rhone anet. G. P. Monnet et Cartier. The manufacture of new compounds from phenetidine and its homologues. Dec. 23.

5490. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of di-iodo-salicylic acid. Jan. 13.

7898. H. H. Lake.—From L. von Lorentz. Process for raising permanent pure cultivations of lactic acid bacteria. Jan. 13.

22,139. M. Dinesman. Process for the manufacture of substitutes for natural musk. Jan. 6.

25,786. A. J. Boulton.—From L. Fromm and R. Schmidt. Vegetable extracts and the method of obtaining the same. Jan. 13.

### XXI.—PHOTOGRAPHY.

#### APPLICATIONS.

29,437. E. Edwards.—From O. Mohr. An improved process for making photographic negatives. Complete Specification. Dec. 22.

30,161. M. Jolles and L. Lilienfeld. The manufacture of an improved photographic printing paper or the like. Dec. 31.

### XXII.—EXPLOSIVES, MATCHES, Etc.

#### APPLICATIONS.

28,889. G. Kynoch and Co., Ltd., and A. T. Cocking. Improvements in explosives. Dec. 16.

28,890. G. Kynoch and Co., Ltd., and A. T. Cocking. Improvements in the manufacture of nitroglycerine. Dec. 16.

1897.

651. W. Greaves and E. M. Hann. Improvements in or relating to explosives. Jan. 9.

1154. F. W. Jones. Improvements in the manufacture of explosives. Complete Specification. Jan. 15.

# LIST OF COUNCIL AND OFFICERS.

## *President.*

Dr. Edward Selmeck, F.R.S., Kersal, Manchester.

## *Vice-Presidents.*

Chas. Dreyfus, Clayton, Manchester.

Dr. A. Dupré, F.R.S., Caxton Street, Westminster, S.W.

Prof. A. K. Huntington, King's College, Strand, W.C.

Boverton Redwood, 4, Bishopsgate Street Within, London, E.C.

Sir H. E. Roseoe, F.R.S., 10, Braugham Gardens, Kensington, S.W.

A. Gordon Salamon, 1, Fenchurch Avenue, E.C.

E. C. C. Stanford, Glenwood, Dalnuir, N.B.

G. N. Stoker, Laboratory, Somerset House, Strand, W.C.

Dr. T. E. Thorpe, F.R.S., 61, Ladbrooke Grove, Notting Hill, W.

Prof. W. A. Tilden, F.R.S., 9, Ladbrooke Gardens, Notting Hill, W.

Thomas Tyrer, Stirling Chemical Works, Stratford, E.

## *Ordinary Members of Council.*

Geo. Beilby, St. Kitts, Sleaford, N.B.

R. Forbes Carpenter, Prestwich, Greencroft Gardens, West Hampstead, N.W.

R. Le Neve Foster, The Firs, North Road, Droylsden, Manchester.

Oscar Guttman, 18 Aberlure Gardens, South Hampstead, N.W.

Douglas Herman, Eccleston Park, Prescot, Lancashire.

David Howard, Devon House, Buckhurst Hill, Essex.

C. C. Hutchinson, 3 Harcourt Buildings, Temple, E.C.

Ivan Leviostein, Minshull Street, Manchester.

J. S. McArthur, 108A, Hope Street, Glasgow.

B. E. R. Newlands, 27, Mincing Lane, E.C.

Sir Robt. Pullar, Perth, N.B.

Wm. Thorp, 24, Crouch Hall Road, Crouch End, N.

## *Chairmen and Secretaries of Sections (Ex-officio Members of Council).*

### *Liverpool:*

Chairman... Dr. Charles A. Kohn, University College, Liverpool.

Secretary... Dr. T. L. Bailey, University College, Liverpool.

### *London:*

Chairman... Dr. R. Messel, 53, Ebury Street, S.W.

Secretary... John Heron, 110, Fenchurch Street, E.C.

### *Manchester:*

Chairman... George E. Davis, Sandilands, Knutsford, Cheshire.

Secretary... J. Carter Bell, Bank House, Higher Broughton, Manchester.

### *Newcastle:*

Chairman... F. S. Newall, Washington, Co. Durham.

Secretary... Saville Shaw, Durham College of Science, Newcastle-on-Tyne.

### *New York:*

Chairman... Dr. C. F. Chandler, School of Mines, Columbia University, New York, U.S.A.

Secretary... Dr. H. Schweitzer, 77, William Street, New York, U.S.A.

### *Nottingham:*

Chairman... F. J. R. Canull, 84, Argyll Terrace, Derby.

Secretary... J. T. Wood, 29, Musters Road, West Bridgeford, Nottingham.

### *Scotland:*

Chairman... Dr. John Clark, 138, Bath Street, Glasgow.

Secretary... Thos. Gray, 204, George Street, Glasgow.

### *Yorkshire:*

Chairman... Thos. Fairley, 17, East Parade, Leeds.

Secretary... H. R. Procter, Thornleigh, Ilkley, Yorks.

## *Honorary Treasurer.*

E. Rider Cook, East London Soap Works, Bow, E.

## *Honorary Foreign Secretary.*

Dr. Ludwig Mond, F.R.S., 20, Avenue Road, Regent's Park, N.W.

## *General Secretary.*

Chas. G. Cresswell, Palace Chambers, Westminster, S.W.

## *Editor.*

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

# LIST OF MEMBERS.

## A

- Abbott, John, 6, Chichester Terrace, Brighton, Chemical Manufacturer.
- Abel, Sir F. A., Bart., F.R.S., 2, Whitehall Court, London, S.W., Consulting Chemist.
- Aceland, Sir H. W., Bart., F.R.S., Radcliffe Library, Oxford, Librarian.
- Adams, Arthur, Kelvin House, Edgbaston Road, Smethwick, near Birmingham, Science Lecturer.
- Adams, M. A., Ashford Road, Maidstone, Kent, Public Analyst.
- Adams, Thos. H., Chemical Laboratory, Loco. Dept., Midland Railway, Derby, Assistant Analyst.
- Adamson, G. P., 233, Reeder Street, Easton, Pa., U.S.A., Manufacturing Chemist.
- Adcock, S. R., Minas de Rio Tinto, Provincia de Huelva, Spain, Analytical Chemist.
- Adler, Dr. Leon N., Adler Colour and Chemical Works, 96-98, Maiden Lane, New York, U.S.A., Manufacturing Chemist.
- Adrianee, John S., 126, East 34th Street, New York, U.S.A., Analytical Chemist.
- Affleck, Dr. J., Springfield, Garston, near Liverpool, Alkali Inspector.
- Aitken, Dr. A. P., 57, Great King Street, Edinburgh, Consulting Chemist.
- Aitken, J. B., Gerard's Fold Chemical Works, Widnes, Chemical Manufacturer.
- Akeroyd, F. W., Grosvenor Villa, Batley, Yorks, Oil Refiner.
- Akitt, Thos., c/o Mexican G. & S. Recovery Co., Hermosillo, Mexico; and (Journals) Langbank, Renfrewshire, Chemist.
- Albright, G. S., The Elms, Park Road, Edgbaston, Chemical Manufacturer.
- Albright, W. A., Mariemont, Edgbaston, Birmingham, Chemical Manufacturer.
- Alcock, Jno. W., Central Brewery, Mott Street, Birmingham, Maltster and Brewer.
- Aldrick, Edwin John, 53, Alpha Road, West Ferry Road, Millwall, E., Chemical Works Clerk.
- Alexander, W. T., 20, Booth Street, Mosley Street, Manchester; and Crummock Bank, Victoria Crescent, Eccles, Drysalter.
- Allan, F. H., Tielke, Portobello House, Wakefield, Analytical Chemist.
- Alldred, C. H., 8, St. Margaret's Road, Plumstead Common, Kent, Analytical Chemist.
- Allen, A. H., Broomfield Road, Sheffield, Consulting Chemist.
- Allen, Edw. W., Dover Mills, Glossop, Derbyshire, Paper Stainer's Manager.
- Allen, G. J., Laboratory, 55-56, Barton Arcade, Manchester, and (Journals) Stonelan, Swinton Park, near Manchester, Analytical and Consulting Chemist.
- Allen, J., 164, Upper North Street, Poplar, London, E., Manufacturing Chemist.
- Allen, R. L., Newton Farm, Middlewich, Cheshire, Analytical Chemist.
- Allen, Walter S., 34, South Sixth Street, New Bedford, Mass., U.S.A., Chemist.
- Allen, Walter W., c/o The Pueblo Smelting and Refining Co., Pueblo, Colorado, U.S.A., Metallurgical Manager.
- Allen, Wm., Evenley Hall, Brackley, North Hants.
- Allhusen, A., Gateshead-on-Tyne, Chemical Manufacturer.
- Allibon, G. H., c/o Richardson Bros. & Co., 30, Donegall Place, Belfast, Chemical Works Manager.
- Alliott, J. B., Messrs. Manlove, Alliott, and Co. Ltd., Nottingham, Mechanical Engineer.
- Allison, Wm. O., 72, William Street, New York, U.S.A., Publisher of "Oil Paint and Drug Reporter."
- Alpiar, Agop, Smyrna, Asia Minor, Morphia Manufacturer.
- Alsberg, M. (Soodheim, Alsberg, & Co.), P.O. Box 2437, New York, U.S.A., Colour Manufacturer.
- Anderson, Robt. T. R., 618, Gallowgate Street, Glasgow, Technical Chemist.
- Anderson, W. Carriek, jun., Mavisbank, Partick Hill, Glasgow, University Chemical Assistant.
- Anderson, Wm., 47, Regent Arch, Edinburgh, Drysalter.
- Anderton, G. H., Howendyke, Howden, Yorks, Chemical Manufacturer.
- Audreoli, Gabriel, 147, Coldharbour Lane, London, S.E., Electro-chemist.
- Andrews, C. W., c/o The John Crerar Library, Wabash Avenue and Washington Street, Chicago, Ill., U.S.A., Chemical Instructor.
- Angell, J., 6, Beaconsfield, Derby Road, Withington, Manchester, Chemical Lecturer.
- Annandale, C. J. R., The Briary, Shotley Bridge, Co. Durham, Paper Maker.
- Annandale, J. H., Polton, Midlothian, N.B., Paper Maker.
- Annison, R. H., 16, Water Lane, Tower Street, London, E.C., Master Lighterman.
- Ansbacher, L. A., P.O. Box 1934, New York, U.S.A., Colour Manufacturer.
- Ansdell, G., 3, Cross Lane, St. Mary-at-Hill, E.C., Analytical Chemist.
- Ansdell, T. C., Kearsley Cottage, Farnworth, Bolton, Manufacturing Chemist.
- Anselm, Dr. Fritz, c/o Actien Gesellschaft für Anilin Fabrikation, Treptowerbrücke 33, Berlin, S.O., Colour Chemist.
- Appleby, Prof. W. R., 911, 5th Street, S.E., Minneapolis, Minn., U.S.A., Professor of Mining and Metallurgy.
- Appleton, H. A., 33, Upper Rushton Road, Thornbury, Bradford, Yorks, Analytical Chemist.
- Archbutt, L., The Yews, Madeley Street, Derby, Analytical Chemist.
- Arding, Francis, 5, Jeffreys Square, St. Mary Axe, London, E.C., Secretary to Ammonia Gas Purification Co., Ltd.
- Armstrong, Rt. Hon. Lord, F.R.S., Newcastle-upon-Tyne, Civil Engineer.
- Asceugh, Jesse, The Grange, Laurel Road, Handsworth, Birmingham, Borax Manufacturer.
- Ashton-Bost, W.D., Cartvale Chemical Works, Paisley, N.B., Chemical Manufacturer.
- Ashwell, H., 91, Waterloo Crescent, Nottingham, Bleacher and Dyer.
- Ashwell, J. H., 91, Waterloo Crescent, Nottingham, Bleacher and Dyer.
- Ashworth, Arthur, Fernhill Chemical Works, Bury, Lancashire, Chemical Manufacturer.
- Ashworth L., The Orchard, Manchester Road, Bury, Lancashire, Bleacher, Dyer, and Finisher.

Atkins, C. E., East Ham House, East Ham, Essex, Chronometer Maker.  
 Atkinson, A. J., 44, Loudoun Square, Cardiff, Analytical Chemist.  
 Atkinson, R. W., 44, Loudoun Square, Cardiff, Technical Chemist.  
 Attfield, Dr. J., F.R.S., Ashlands, Watford, Hertfordshire, Chemical Consultant and Analyst.  
 Auchterlonie, Wm., jun., Canal Bank House, Paisley, N.B., Analytical Chemist.  
 Auer, Dr. H., V. Sas Utea 10, Budapest, Hungary, Technical Chemist.  
 Austen, Prof. Peter T., 99, Livingston Street, Brooklyn, N.Y., U.S.A., Professor of Chemistry.  
 Aykroyd, H. E., Thornfield, Duckworth Lane, Bradford, Yorks, Dyer.

## B

Bache, Arthur E., 15, Dornburg Road, Blackheath, S.E., Sanitary Engineer.  
 Bachke, Anton S.O., Røros Vaerke, Røros, Norway, Metallurgical Engineer.  
 Bacon, Nathaniel T., Peace Dale, Rhode Island, U.S.A., Chemical Engineer.  
 Bailey, Edwin M., 6, Pumphierston, Midezlder, N.B., Technical Chemist.  
 Bailey, Dr. G. H., Marple Cottage, Marple, Cheshire, Chemical Lecturer.  
 Bailey, Dr. T. L., University College, Brownlow Street, Liverpool, Lecturer on Technological Chemistry.  
 Bailey, Sir W. H., Albion Works, Salford, Manchester, Chemical Engineer.  
 Bailey, Walter P., 29, Segismundo Moret, Cadiz, Spain, Chemist.  
 Baird, H. Harper, 14, Cross Street, Hatton Garden, London, E.C., Laboratory Furnisher.  
 Baird, Wm., c/o Lewis Berger and Sons, Ltd., Homerton, N.E., Technical Chemist.  
 Baird, W. Raymond, 271, Broadway, New York, U.S.A., Patent Lawyer.  
 Bairstow, John, Barley, Queen's Park, Chester, Chemical Works Manager.  
 Baker, Harry, Epworth House, Moughland Lane, Runcorn, Analytical Chemist.  
 Baker, Julian L., Stamford, Headham Road, Upper Tooting, S.W., Sugar Chemist.  
 Baker, Theodore, Box 97, Belford, N.J., U.S.A., Analytical Chemist.  
 Bale, Fred., Coventry Hospital, Droitwich, Science Teacher and Chemist.  
 Ballard, Ernest, Colwall, Great Malvern, Malt Vinegar Brewer.  
 Ballard, E. G., Newton Lane, Hoole, Chester, Alkali Works Inspector.  
 Ballantyne, H., 75, Chancery Lane, London, W.C., Analytical Chemist.  
 Ballinger, Jno., Free Library, Cardiff, Librarian.  
 Baly, E. C. C., University College, Gower Street, W.C., Analytical Chemist.  
 Bamber, H. K., 9, Victoria Street, London, S.W., Consulting Chemist.  
 Bamber, H. K. G., c/o Knight, Bevan, and Sturge, Northfleet, Kent, Cement Works Chemist and Manager.  
 Banister, H. C., Elmhurst, Blundellsands, near Liverpool, Chemical Works Manager.  
 Banks, Arthur J., c/o F. W. Fellowes, 62, Chancery Lane, London, W.C., Brewer's Analyst.  
 Banks, Jno. H., c/o Ricketts and Banks, 104, John Street, New York, U.S.A., Mining Engineer.  
 Bannan, John F., North Andover, Mass., U.S.A., Chemist (Woollen Mill).  
 Banner, Samuel, 4, Ivanhoe Road, Liverpool, Petroleum Merchant.  
 Bannister, R., The Laboratory, Somerset House, London, W.C., Analytical Chemist.  
 Bannister, W., Victoria Lodge, Cork, Ireland, Manufacturing Chemist.  
 Barbour, Sam., c/o F. H. Faulding and Co., Adelaide, South Australia, Manufacturing Chemist.  
 Barbour, T. F., 37, Berkeley Terrace, Glasgow, Chemist.  
 Barclay, H., Calder Ironworks, Coatbridge, N.B., Ironworks Manager.  
 Barden, Alf., Far Bank, Shelley, near Huddersfield, Glue and Size Maker.  
 Barden, Sam., Far Bank Farm, Shelley, near Huddersfield, Glue and Size Manufacturer.  
 Bardsley, Robt., Messrs. Jewsbury and Brown, Ardwick Green, Manchester, Mineral Water Manufacturer.  
 Bardwell, Fred. L., Massachusetts Institute of Technology, Boston, Mass., U.S.A., Assistant Professor of Chemistry.  
 Barford, E. A., 3, Brook Street, Luton, Beds, Straw Plait Dyer and Bleacher.  
 Barlow, Clinton W., 38, Irving Place, Brooklyn, N.Y., U.S.A., Merchant.  
 Barnes, Edw. A., Dynamite Works, Zuurfontein, S.A.R., Technical Chemist.  
 Barnes, H. J., Phoenix Chemical Works, Hackney Wick, E., Manufacturing Chemist.  
 Barnes, J., Marl Terrace, Accrington, Lancashire, Analytical Chemist.  
 Barnes, Jonathan, 1, Trafalgar Street, Great Clowes Street, Manchester, Analytical Chemist.  
 Barr, J., Dinting Vale, Dinting, Derbyshire, Chemical Manager.  
 Barraclough, T. C., 20 Bucklersbury, London, E.C., Analytical Chemist.  
 Barraclough, Wm. H., Harebort Lodge, Chapelton, Sheffield, Engineer.  
 Barratt, J. Treeby, Bronheulog, Mostyn, North Wales, Chemist and Manager.  
 Barrett, Arthur A., 185, Corso Vittorio Emanuele, Messina, Sicily, Manufacturer of Essential Oils.  
 Barrie, D. McLaurin, c/o New Primrose G. M. Co., Germiston, Johannesburg, S.A.R., Analytical Chemist.  
 Barrington, Edw. C., 18, Earlsfort Terrace, Dublin, Ireland, Soap Manufacturer.  
 Barton, G. E., c/o Whitall, Tatum, and Co., Flint Glass Works, Millville, N.J., U.S.A., Technical Chemist.  
 Baskerville, Dr. Chas., University of North Carolina, Chapel Hill, N.C., U.S.A., Assistant Professor of Chemistry.  
 Bassett, H., 26, Belitha Villas, Barnsbury, N.  
 Batchelor, Telford C., 8, Baron's Court Road, West Kensington, W., Mechanical Engineer.  
 Bate, William, c/o National Explosives Co., Ltd., Hayle, Cornwall, Technical Chemist.  
 Bateman, Jno., c/o J. C. and J. Field, Lim., Lambeth Marsh, S.E., Candle and Acid Works Manager.  
 Bateman, R. W., 90, Cazenove Road, Stoke Newington, N., Leather Manufacturer.  
 Bateson, Percy, Cuckoo Lane, Gateacre, near Liverpool, Technical Chemist.  
 Batty, R. B., Wharfedale, Erdington, near Birmingham, Nickel Works Manager.  
 Baum, Henry, 145, Dickenson Road, Rusholme, Manchester, Chemist.  
 Bayas, Aug de, Foster's Brewery, Collingwood, Melbourne, Australia, Brewer.  
 Baxter, W. H., 11, High Road, Streatham, S.W., Brewery Manager.  
 Baynes, J., Royal Chambers, Seale Lane, Hull, County and Borough Analyst.  
 Beach, E. J., 1183, Locust Street, Dubuque, Iowa, U.S.A., Soap Manufacturer.  
 Beadle, Clayton, 60, West Street, Erith, Kent; and The Rookery, Belvedere, Kent (Journals), Consulting Chemist.  
 Bealey, Adam C., c/o R. Bealey & Co., Radcliffe, Lancashire, Bleacher and Alkali Manufacturer.  
 Beanes, E., Moatlands, Paddock Wood, Kent, and (Journals) 119, Ashley Gardens, London, S.W., Manufacturing Chemist.  
 Beaven, E. S., 5, Boreham Terrace, Warminster, Wilts, Malster.

- Bechl, Guilo de, 43, Rue de la Chaussée D'Antin, Paris, France, Director of the "Société la Saturnine."
- Beck, H., 22, Bush Lane, E.C., Chemical Agent.
- Beckett, G. H., c/o M. Nobel, San Remo, Italy, Analytical Chemist.
- Beckett, J. H., Corbar Hill House, Bixton, Manufacturing Chemist.
- Bechel, Lazin A., Met. all Post Office, Parish of Ascension, Louisiana, U.S.A., Sugar Engineer.
- Bedford, Chas. S., Broomfield, Chapel Lane, Headingley, Leeds, Manufacturing Chemist.
- Bedford, J., Woodhouse Cliff, Leeds, Chemical Manufacturer.
- Bedford, Jas. E., Messrs. Wood and Bedford, Kirk-stall Road, Leeds, Manufacturing Chemist.
- Bedon, Prof. P. P., Durham College of Science, Newcastle-on-Tyne, Professor of Chemistry.
- Beilly, G., St. Kitts, St. Kitts, N.B., Chemical Engineer.
- Bell, C., Lowthian, Free Library, Middlesbrough-on-Tees, Soda and Iron Manufacturer.
- Bell, Sir Lowthian, Bart., F.R.S., (Journals) Rounton Grange, Northlerton; and (subs.) c/o Bell Bros., Middlesbrough, Iron and Chemical Manufacturer.
- Bell, J. Carter, Bank House, The Cliff, Higher Broughton, Manchester, Public Analyst.
- Bell, J. Ferguson, Stafford, Gas Engineer.
- Bell, T. Hugh, Middlesbrough-on-Tees, Soda and Iron Manufacturer.
- Bendix, D., The British Alizarin Co., Limited, Silvertown, Victoria Docks, London, E.; Journals to 371, Romford Road, Forest Gate, E., Managing Chemist.
- Benger, F. B., The Grange, Knutsford, Cheshire, Manufacturing Chemist.
- Benjamin, Dr. M., Smithsonian Institution, Washington, D.C., U.S.A., Consulting Chemist, A.M., Ph.D.
- Bennett, Thos., Birch Vale, near Stockport, Calico Printer.
- Bennie, J. W., 3, Park Place, Maze Hill, Greenwich, S.E., Metallurgist.
- Bertz, Ernest, 5, Demesne Road, Whalley Range, Manchester, Lecturer on Dyeing.
- Beringer, J. J., Basset Road, Camborne, Cornwall, Metallurgist.
- Berk, Fred. W., 1, Fenchurch Avenue, London, E.C., Chemical Manufacturer.
- Bernard, Jas., jun., Casal das Rollas, Oliveira, Lisbon, Chemical Works Manager.
- Bernays, J., 96, Newgate Street, London, E.C., Civil Engineer.
- Berry, E. E., Casa Balestra, Bordighere, Italy, Technical Chemist.
- Berry, G. F., Atlas Chemical Works, West Ferry Road, Millwall, E., Chemical Works Manager.
- Bertram, H. Conrad, c/o Josiah Macy's Sons, 191, Front Street, New York, U.S.A., Oil Refiner.
- Best, Dr. T. T., Hardshaw Brook Chemical Works, St. Helens, Lancashire, Technical Chemist.
- Bevan, E. J., 4, New Court, Lincoln's Inn, London, W.C., Public Analyst and Consulting Chemist.
- Bevan, S. Howel, Hillside, Llanelli, South Wales, Chemical Engineer.
- Beveridge, J., Linelle, Old Road West, Gravesend, Pulp and Paper Manufacturer.
- Bhaduri K., c/o S. K. Lahiri and Co., 54, College Street, Calcutta, India, Analytical Chemist.
- Bibby, E. V., Garston Copper Works, Garston, near Liverpool, Copper Smelter.
- Bibby, John, 92, Orrell Lane, Aintree, Liverpool, Student.
- Bickerdike, W. E., Clayton Grange, Wiltshire, near Blackburn, Manufacturing Chemist.
- Bicknell, G. Arthur, 839, East Madison Avenue, Cleveland, Ohio, U.S.A., Analytical Chemist.
- Biggart, J. Wm., 29, Cathcart Street, Greenock, N.B., Analytical Chemist.
- Biggart, Wm. L., Messrs. C. M. Biggart and Co., 15, Gordon Street, Glasgow, Public Analyst.
- Biggs, B., Vestry House, Lawrence Pountney Hill, London, E.C., Chemical Merchant.
- Bihn, G. F., Pennsylvania Salt Manufacturing Co., Philadelphia, U.S.A., Chemical Manufacturer.
- Billing, H. S., 5, Regent Terrace, Plympton, South Devon, Analytical and Managing Chemist.
- Billings, Edgar F., 165, High Street, Boston, Mass., U.S.A., Manufacturing Chemist.
- Billington, Chas., jun., Wolstanton, Staffordshire, Brass Founder.
- Bindschedler, Dr. R., Basle Chemical Works Bindschedler, Basle, Switzerland, Colour Manufacturer.
- Binney, H. A., Rainhill, near Liverpool, Glass Manufacturer.
- Birch, Wm., Milton Street Ironworks, Lower Broughton, Manchester, Machinist.
- Bird, Arthur W., 26, Westbourne Terrace Road, London, W., Chemist.
- Bird, Henry, South Down House, Millbrook, Plymouth, Metallurgist.
- Bird, Jno. B., Minver House, Bateman Street, Cambridge, Manure Manufacturer.
- Bird, R., Eilerslie, Roath, Cardiff, Tar Distiller.
- Bird, Wm. R., 12, Gordon Road, New Swindon, Wilts, Analytical Chemist.
- Birley, R. K., Messrs. Chas. Macintosh & Co., Cambridge Street, Manchester, India-rubber Manufacturer.
- Bischof, Gustav, 4, Hart St., Bloomsbury, London, W.C., Technical Chemist.
- Bischoff, Dr. Ernst, 227, East 19th Street, New York, U.S.A., Chemist.
- Bishop, A. Conway, Three Mills Lane, Bromley-by-Bow, London, E., Manufacturing Chemist.
- Bishop, Fred, c/o Burmah Oil Co., Rangoon, Burmah, Technical Chemist.
- Bishop, G. A., Gartverrie Fireclay Works, Coatbridge, N.B., Mining Engineer.
- Bishop, Jos. T. F., 123, Cottenham Street, Chorlton-on-Medlock, Manchester, Agent.
- Black, Wm., Stanrigg, Airdrie, N.B., Coal Master.
- Black, Wm., 9, St. Edmund's Road, Gateshead, Analytical Chemist.
- Blackmore, H. S., 206, South Ninth Avenue, Mount Vernon, N.Y., U.S.A., Chemist (Pure Aluminium and Chemical Company).
- Blagden, Victor, 50-51, Lime Street, London, E.C., Chemical Merchant.
- Blagden, W. G., 4, Fenchurch Avenue, London, E.C., Chemical Merchant.
- Blake, C. A., 47, Piccadilly, London, W., Pharmaceutical Chemist.
- Blake, Jas., Thames Sugar Refinery, Silvertown, London, E., Sugar Refinery Manager.
- Blakey, A. J., Dudbridge Mills, Stroud, Gloucestershire, Foreman Dyer.
- Blas, Edw., Essen (Ruhr), Germany, Civil Engineer.
- Bleas, John, c/o Laugworthy Bros. and Co., Lim., Greengate Mills, Salford, Dyer and Calico Printer.
- Blenkinsop, W., Garden Wharf, Battersea, London, S.W., Manufacturing Chemist.
- Bles, A. J. S., 32, Chorlton Street, Manchester, Chemical Merchant.
- Bloede, Victor G., Carroll Station, Baltimore, Md., U.S.A., Manufacturing Chemist.
- Bloomer, Fred. J., 15, Broderick Road, Tooting, S.W., Technical Chemist and Nickel Works Manager.
- Bloomfield, R., Telhara Factory, via Dhaka Chumparun, Bengal, India, Indigo Planter.
- Blount, Bertram, Chemical Laboratory, Broadway, Westminster, S.W., Analytical Chemist.
- Bloxam, A. G., The Goldsmiths' Institute, New Cross, S.E., and (Journals) 16, Bolingbroke Road, West Kensington, W., Analytical Chemist.
- Bloxam, W., Popplewell, Royal Naval College, Greenwich, S.E., Chemist.
- Blundstone, E. R., 14, Great Smith Street, Westminster, S.W., and (Journals) Cornwall Lodge, St. James' Road, New Hampton, Middlesex, Consulting and Analytical Chemist.
- Blyton, J., 12, Cromford Court, Market Street, Manchester.
- Boake, A., Warton Road, Stratford, E., Manufacturing Chemist.
- Boake, Edmund J., 11, Christchurch Road, Crouch End, N., Manufacturing Chemist.

- Board, J. T., Distillery, Cheese Lane, Bristol, Distiller.
- Böhm, Jos. A., c/o Aetien Gesellschaft für Chemische Industrie, Mannheim, Germany, Manager.
- Bookman, Dr. S., 9, East 62nd Street, New York, U.S.A., Chemist.
- Boor, Leonard G., 1 and 2, Artillery Lane, London, E.C., Chemical Merchant.
- Boot, John C., Brooklyn Distilling Co., Kent Avenue, Brooklyn, N.Y., U.S.A., Chemist.
- Booth, F. W., Station Road, Whittington Moor, near Chesterfield, Analytical Chemist.
- Booth, Geo., Irk Vale Dyeworks, Middleton, near Manchester, Yarn Dyer.
- Booth, Robt., 110, Cannon Street, London, E.C., Engineer.
- Boothby, Chas., 9, Tyndall Road, Leyton, E., Analytical Chemist.
- Borland, John, Etruria, Kilmarnock, N.B., Pharmaceutical Chemist.
- Borland, W. D., Beacon Lodge, Green Street Green, near Dartford, Kent, Explosives Chemist.
- Bothamley, C. H., Wentworth, Weston-super-Mare, Somerset, County Director of Technical Instruction.
- Bott, Dr. Wm., Singapore, S.S., Science Lecturer.
- Böttinger, H. T., Elberfeld, Germany; and (subs.) c/o Bryce and Rumpff, 20, Booth Street, Manchester, Colour Manufacturer.
- Bottle, Alex., 4, Godwyne Road, Dover, Pharmaceutical Chemist.
- Boulton, H. E., 64, Cannon Street, London, E.C., Chemical Manufacturer.
- Boulton, James, Crayford Mills, Stratford, E., Manufacturing Chemist.
- Boulton, S. B., 64, Cannon Street, London, E.C., Chemical Manufacturer.
- Boulton, T. S., 14, Freegrove Road, Caledonian Road, N., Manager.
- Bow, R. H., 7, South Gray Street, Edinburgh, Civil Engineer.
- Bowen, S. B., Brickfield Chemical Works, Llanelli, South Wales, Chemical Manufacturer.
- Bower, Frank, 164, Marylebone Road, London, N.W., Analytical Chemist.
- Bowes, Harry, 53, Moss Bank, Higher Crumpsall, Manchester, Analytical Chemist.
- Bowing, Jno., Fuel Works, Tilbury, Essex, Manufacturing Chemist.
- Bowley, Jos. John, Wellington Works, Battersea Bridge, London, S.W., Chemical Manufacturer.
- Bowman, Dr. F. H., Mayfield, Knutsford, Cheshire, Chemical Manufacturer.
- Bowman, Jas. H., Canada Chemical Manufacturing Co., London, Ont., Canada, Professor of Chemistry.
- Bowman, R., Chemical Director of Works.
- Bowman, Prof. Walker, c/o Louisville Spirit-Cured Tobacco Co., Louisville, Kentucky, U.S.A., Professor of Chemistry.
- Bowman, Wm. P., 7, White Horse Street, Leeds, Wholesale Druggist.
- Bowrey, J. J., Kingston, Jamaica, West Indies; and (subs.) 28, Belmont Road, Ilford, Essex, Analytical Chemist.
- Boyce, Frank, c/o Goodall, Backhouse, and Co., White Horse Street, Leeds, Technical Chemist.
- Boyd, Pythagoras, 72, Marshall Street, North Adams, Mass., U.S.A., Print Works Superintendent.
- Boyd, W., Tharsis Co.'s Works, Hebburn-on-Tyne, Chemical Engineer.
- Boyd, W., Anson Street, Rugeley, Staffordshire, Technical Chemist.
- Bradburn, J. A., 1816, West Genesee Street, Syracuse, N.Y., U.S.A., Chemical Engineer (Ammonia Soda Manufacture).
- Bradbury, A., Queen Buildings, 11, Dale Street, Liverpool, Chemical Broker.
- Bradford, Henry, c/o E. G. Clayton, 32, Holborn Viaduct, E.C., Analytical Chemist.
- Bradley, Edw. F., The Star Brush Co., Ltd., Eden Grove, Holloway, N., Engineer.
- Bragg, Everett B., 242, Kennard Street, Cleveland, Ohio, U.S.A., Manufacturing Chemist.
- Braithwaite, Isaac, Kendal, Westmoreland, Drysalter.
- Bramham, W., 115, Bow Road, London, E., Chemical Engineer.
- Bramwell, Major E., Ethersall, Huyton, near Liverpool, Chemical Manufacturer.
- Bramwell, Sir F., Bart., F.R.S., 5, Great George Street, Westminster, London, S.W., Civil Engineer.
- Bramwell, G. H., Cowley Hill, St. Helens, Lancashire, Alkali Manufacturer.
- Branson, F. W., Wynneholme, Far Headingley, Leeds, Pharmaceutical Chemist.
- Bray, Daniel, Broadmoor Chemical Works, Cinderford, Gloucestershire, Chemist and Managing Partner.
- Bray, Geo., Bagby Fields, Leeds, Gas Lighting Engineer.
- Breen, George, c/o Irvine Chemical Co., Ltd., 204, St. Vincent Street, Glasgow, Chemical Works Manager.
- Brellitt, Wm., Glasshoughton, Castleford, Yorks, Glass Manufacturer.
- Breneman, Dr. A. A., 97, Water Street, New York, U.S.A., Analytical Chemist.
- Bressey, Edw., 209, Romford Road, Stratford, E., Gold and Silver Refiner.
- Breyer, Theodor, 105, Main Street, Peoria, Ill., U.S.A., Chemist (American Glucose Co.).
- Briant, L., 24, Holborn Viaduct, London, E.C., Analytical Chemist.
- Brierley, J. T., 249, Bolton Road, Chorley, Lancashire, Analytical Chemist.
- Briggs, J. Burnett, Vauxhall Soap Works, 6, Blackstock Street, Liverpool, Soap Manufacturer.
- Briggs, J. F., Sakri, near Darbhanga, Behar, India, Sugar Works Chemist.
- Briggs, T. Lynton, 357, Madison Street, Brooklyn, New York, U.S.A., Technical Chemist.
- Briggs, W., 4, Erskine Terrace, Dundee, Manufacturing Chemist.
- Brindley, G. F., c/o Niagara Electro-Chemical Co., Niagara Falls, N.Y., U.S.A., Chemical Engineer.
- Bristed, John (Journals); c/o Messrs. Kemp and Co., Bombay, India; and (subs.) H. B. Sleeman, 84, Leadenhall Street, E.C., Manager.
- Bristow, G. W., Worcester House, 35, Eastcheap, London, E.C., Chemical Manager.
- Broadbent, H., c/o Goodall, Backhouse, & Co., Sovereign Street, Leeds, Chemist.
- Broadhurst, W. Homer, 294, Lafayette Avenue, Brooklyn, N.Y., U.S.A., Chemist.
- Brock, Arthur, Messrs. C. T. Brock & Co., South Norwood, S.E., Firework Manufacturer.
- Brock, J., Gwern-Tyno, Colwyn Bay, North Wales, Chairman of United Alkali Co., Ltd.
- Brooke, C. B., jun., Colne House, Brantham, near Manningtree, Xylonite Manufacturer.
- Brooke, Edwd., Fieldhouse, Huddersfield, Fireclay Manufacturer.
- Brooke, S. W., Colne House, Brantham, near Manningtree, Xylonite Manufacturer.
- Brooke, Wilton, Ashville, Stairfoot, Barnsley, Yorks, Manufacturing Chemist.
- Brookes, E. A., 31, Bamford Road, Didsbury, near Manchester, Analytical Chemist.
- Brookman, Fred. W., 176, Ramsay Street, Rochdale, Manure Works Manager.
- Broome, F. J., Holloway, near Matlock, Derbyshire, Assayer.
- Brothers, H. E., Park Terrace, Tunstall, Stoke-on-Trent, Analyst.
- Brothers, Wm., 16, Manchester Road, Bury, Lancashire, Chemical Manufacturer.
- Brotberton, E. A., Commercial Buildings, Leeds, Ammonia Distiller.
- Brown, Prof. A. Crum, F.R.S., 8, Belgrave Crescent, Edinburgh, Professor of Chemistry.
- Brown, Caesar R., Anglo-Continental Guano Works, Victoria Docks, E., Works Foreman.
- Brown, D., 93, Abbey Hill, Edinburgh, Chemical Manufacturer.
- Brown, D., Donaghmore, Tyrone, Ireland, Soap Manufacturer.

- Brown, Edw., Russian Steam Oil Mills, 22, Kourland-ky Street, St. Peter-burg, Analytical Chemist.
- Brown, F. W., 43, Elgin Avenue, Maida Hill, W.
- Brown, G. E., Great Western Railway Laboratory, Swindon, Chemist.
- Brown, H., Cannon Brewery, Watford, Herts, Brewing Chemist.
- Brown, Horace T., F.R.S., 52, Neven Square, Kensington, S.W., Brewing Chemist.
- Brown, Jas., Kimberley Gardens, Bloomfield, Belfast, Ireland, Brewer.
- Brown, Dr. J. Campbell, 8, Abercromby Square, Liverpool, Professor of Chemistry.
- Brown, J. Henry, c/o Bowman, Thompson, & Co., Ltd., Northwich, Technical Chemist.
- Brown, Ophiant A., Lennoxmill, Lennoxtown, N.B., Print-works Manager.
- Brown, Reginald B., 18, Warwick Place, Leeds, Dyer's Chemist.
- Brown, Robt., The Firs, Hartford, Northwich, Engineer.
- Brown, R. J., Technical School, Stockport, Principal.
- Brown, T., The Chemical Works, King's Lynn, Chemical Manufacturer.
- Brown, W., Aitcheson, Tudor Oil Works, Port Elizabeth, Cape Colony, South Africa, Oil Works Manager.
- Brown, Walter, c/o Jas. H. Dennis and Co., Widnes, Assayer.
- Brown, Wm., 14, Warwick Street, Sunderland, Chemist.
- Browne, Augustus F., South Metropolitan Gasworks, 155, Rotherhithe Street, S.E., Gas Engineer.
- Browning, W., Broad Oak, Accrington, Calico Printer.
- Bruce, Jas., The Irish Distillery, Connswater, Belfast, Ireland, Distiller.
- Bruckmann, G. T., 192, 18th Street, Brooklyn, N.Y., U.S.A., Chemical Engineer.
- Brunner, H., Holly Mount, Tarbock Road, Hayton, near Liverpool, Chemical Manufacturer.
- Brunner, H. Bertram, Winnington Old Hall, Northwich, Chemist and Electrician.
- Brunner, J. F. L., 23, Wetherby Gardens, London, S.W., Chemical Manufacturer.
- Brunner, Sir J. T., Bart., M.P., Druid's Cross, Wavertree, Liverpool, Chemical Manufacturer.
- Brunton, J. Dixon, Wire Mill, Musselburgh, N.B., Wire Manufacturer.
- Bryce, John Annan, Messrs. Wallace Bros., 8, Austin Friars, London, E.C., Merchant.
- Bryce, Thos., Tharsis Mines, Huerva, Spain, Chemist.
- Bryce-Smith, N. J., Oakfield, Barrow, Whalley, near Blackburn, Calico Printer.
- Buchan, Alex., Maude Cottage, Pellatt Grove, Wood Green, N., Chemist.
- Buchanan, D. G., Mount Vernon House, Glasgow, Analyst.
- Buchanan, Jas., jun., Caledonia Foundry, Brasenose Road, Liverpool, Engineer.
- Buchanan, Joshua, Buffelsdoorn, via Potchefstroom, S.A.R., Analytical Chemist.
- Budden, E. R., 11, Farnival Street, Holborn, E.C., Consulting Chemist.
- Bull, Johann - C., Erith, Kent, Chemical Engineer.
- Bullock, J. L., 3, Hanover Street, Hanover Square, London, W., Manufacturing Chemist.
- Bunty, H., c/o Millom and Askam Hematite Iron Co., Ltd., Askam-in-Furness, Lancashire, Ironworks Manager.
- Burker, H. E., 1, Deantley Terrace, St. Mary's Road, Newton Heath, Manchester, Technical Chemist.
- Bunting, W., Lightfoot, c/o F. W. Ashton & Co., Hyde, near Manchester, Calico Printer.
- Burbridge, Jas., India-rubber Mills, Tottenham, N., India-rubber Manufacturer.
- Burdekin, G., jun., Park Villa, Prescott Road, St. Helens, Chemical Works Manager.
- Burford, Samuel F., Eastleigh, Queen's Road, Leicester, Analytical Chemist.
- Bürger, Dr. J., 1, Birch Avenue, Talbot Road, Old Trafford, Manchester, Technical Chemist.
- Burgess, Geo., Pittville Terrace, Ditton, Widnes, Chemist.
- Burgess, Herbert, c/o Bevington and Sons, Neckinger Mills, Bermondsey, S.E.; and (Journals) 11, Pendrell Road, Brockley, S.E., Dyer and Chemist.
- Burgess, Herb. E., 16, Bloomsbury Street, London, W.C., Chemist.
- Burgess, Wm. T., Beech Road, Reigate Hill, Surrey, Analytical Chemist.
- Burghardt, Dr. C. A., Fern Cottage, Alderley Edge, Cheshire, Consulting Chemist.
- Burland, Richard O., Bishopgate, Wigan, Manufacturing Chemist.
- Barnard, R., Plymouth Chemical Works, Plymouth, Chemical Manufacturer.
- Burnet, Henry K., North Brook Vitriol Works, Bradford, Yorks, Vitriol Maker.
- Burnham, J. C., Kirkee, near Poona, India, Analytical Chemist.
- Burnham, Mather H., Houghton, Lake Superior, Mich., U.S.A., Mining Engineer.
- Burn-Murdoch, J. V., Elm-tree House, Pembroke, South Wales, Assayer.
- Burrell, B. A., 5, Mount Preston, Leeds, Analytical Chemist.
- Burrough, Horace, jun., 1130, Lafayette Avenue, Baltimore, Md., U.S.A., Technical Chemist.
- Burrows, Edw., Belle Vue Road, Low Fell, Gateshead-on-Tyne, Alkali Works Manager.
- Burton, F., 2, Green Street, Bethnal Green, E., Colour Manufacturer.
- Burton, Wm., Clifton Junction, near Manchester, Potter's Chemist.
- Bury, J. H., Church Chemical Works, near Accrington, Chemical Manufacturer.
- Bush, Baron W. de, 20, Artillery Lane, London, E.C., Chemical Manufacturer.
- Butler, Paul, Lowell, Mass., U.S.A., Ammunition Manufacturer.
- Butler, Samuel, Compton, Wolverhampton, Brewer.
- Butler, W. W., The Cedars, Duchess Road, Edgbaston, Birmingham, Brewer.
- Butterfield, J. C., 13, Victoria Street, Westminster, S.W., Analytical Chemist.
- Butterfield, W. J. A., Ebor House, Redhill, Analytical Chemist.
- Butt, E. N., 77, Hamilton Terrace, Maida Vale, W., Pharmaceutical Chemist.
- Buttfield, Horace V., 13, Wellington Road, Bush Hill Park, Enfield, N., Chemical Demonstrator.
- Byard, A. G., c/o Burt, Boulton, and Heywood, Apartado 8, Bilbao, Spain, Technical Chemist.
- Byrom, T. H., Laboratory, Wigan Coal and Iron Co., Wigan, Analytical Chemist.
- Rythway, M., 43, Lloyd Street, Albert Street, Manchester, Drysalter.

## C

- Cabot, Godfrey L., 82, Water Street, Boston, Mass., U.S.A., Chemist.
- Cadett, Jas., Ashtead, Surrey, Photographic Dry Plate Maker.
- Caines, G. S. A., 7, Rochester Terrace, Camden Road, London, N.W., Analytical Chemist.
- Cairns, F. Irvan, 246, Park Avenue, Bridgeport, Conn., U.S.A., Metallurgist.
- Caldecott, Arthur, Box 1891, Johannesburg, S.A.R., Metallurgist.
- Calderwood, J., Gowanlea, Spencer Park, Wandsworth, S.W.; and Price's Patent Candle Co., Battersea, Candle Manufacturer.
- Caldwell, Wm., Murray Street, Paisley, N.B., Drysalter.
- Calkin, Wm. S., Johnsonburg Quay P.O., Pa., U.S.A., Paper Pulp Works Chemist.
- Cambier, Jacob, c/o C. F. and I. Co., Pueblo, Colo., U.S.A., Chemist.
- Cameron, Alex., Agricultural Laboratory, 4, Lombard Court, E.C., Analytical Chemist.
- Cameron, Jas., 11, Bolton Road, Port Sunlight, near Birkenhead, Chemist.

- Cameron, Peter, Bath Bridge Colour Works, Bristol, Colour Works Manager.
- Cammack, J., 51, Denton's Green Lane, St. Helens, Technical Chemist.
- Campbell, Albert J., Broad Street Avenue, London, E.C., Engineer.
- Campbell, Andrew, c/o Burmah Oil Co., Ltd., Rangoon, Burmah, Analytical Chemist.
- Campbell, Archibald, 42, Whittaker Road, Upton Park, E.; and (Journals) 519, West 18th Street, Erie, Pa., U.S.A., Technical Chemist.
- Campbell, John, 118, Warren Street, New York City, U.S.A., Dye Manufacturer.
- Campbell, Jno. D., 10, St. Mary Axe, London, E.C., Oil Merchant.
- Campbell, Peter, c/o The Nairn Linoleum Co., P.O. Box 32, Newark, N.J., U.S.A., Manager.
- Cannon, J. C., 70, Ham Park Road, Forest Gate, E., Analyst.
- Causton, M., Beaufoy's Chemical Works, Lavender Hill, London, S.W., Vinegar Works Manager.
- Canziani, Enrico, 3, Palace Green, Kensington, W., Civil Engineer.
- Carden, Albert J., Lea Valley Distillery, Warton Road, Stratford, E., Distiller.
- Carey, Arthur, Browside, Gateacre, near Liverpool, Chemist.
- Carey, E., Browside, Gateacre, near Liverpool, Chemical Manufacturer.
- Cargay, W. E., c/o Sclopis and Co., 31, Via Aosta, Torino, Italy, Works Chemist.
- Carlile, T., 23, West Nile Street, Glasgow, Chemical Manufacturer.
- Carlsson, Hugo, c/o The Johnson Co., Lorain, Ohio, U.S.A., Analytical Chemist.
- Carmichael, Dr. H., 12, Pearl Street, Boston, Mass., U.S.A., Analytical Chemist.
- Carmichael, Herbert, Bureau of Mines, Victoria, British Columbia, Public Analyst and Assayer.
- Carmody, Prof. Patrick, Government Laboratory, Port of Spain, Trinidad, Analytical Chemist.
- Caro, Dr. H., Mannheim, Germany, Technical Chemist.
- Carpenter, C. C., Gas Works, Bridge Foot, Vauxhall, S.E., Civil Engineer.
- Carpenter, H. S., Beekington House, Weigh-ton Road, Anerley, S.E., Insurance Broker.
- Carpenter, R. F., Prestwich, Greeneroft Gardens, West Hampstead, N.W., Alkali Works Inspector.
- Carruthers, J. G., Burnbrae House, Milngavie, N.B., Dye-works Manager.
- Carswell, Thos. R., 19, Cheetham Place, Cheetham Hill, Manchester, Analyst and Teacher of Chemistry.
- Carteighe, M., 180, New Bond Street, London, W., Pharmaceutical Chemist.
- Carter, Stewart F., P.O. Box 221, North Adams, Mass., U.S.A., Chemist.
- Carter, W. C., 19, Short Strand, Belfast, Ireland, Analytical Chemist.
- Carulla, F. J. R., 84, Argyll Terrace, Derby, Chemical Manufacturer.
- Case, W. T., 7, Cedar Street, New York, U.S.A., Chemist.
- Castner, Hamilton Y., c/o The Aluminium Co., Ltd., Oldbury, Birmingham, Chemical Engineer.
- Catlin, Chas. A., 133, Hope Street, Providence, R.I., U.S.A., Chemist (Rumford Chemical Works).
- Caven, Robt. M., University College, Nottingham, Lecturer in Chemistry.
- Cawley, G., 29, Great George Street, Westminster, S.W., Chemical Engineer.
- Cawley, J., 278, Passaic Street, Newark, N.J., U.S.A., Analytical Chemist.
- Chadwick, Walter M., 24, West 3rd Street, Bayonne, N.J., U.S.A., Chemical Works Manager.
- Chaloner, G., 30, Weston Park, Crouch Eod, N., Chemical Lecturer.
- Chaloner, G. W., Niagara Works, Eagle Wharf Road, London, N., Chemical Manager.
- Chance, A. M., Lawnside, Edgbaston, Birmingham, Chemical Manufacturer.
- Chance, J. F., 51, Prince's Gate, London, S.W., Chemical Manufacturer.
- Chandler, Dr. C. F., School of Mines, Columbia University, New York, Professor of Chemistry.
- Chaplin, Dr. Edw. M., 60, Westgate, Wakefield, Yorks., Analytical Chemist.
- Chapman, Alf. C., East India Chambers, 23, Leadenhall Street, E.C., Analytical Chemist.
- Chapman, S., 36, Mark Lane, E.C., Chemical Manufacturer.
- Charlier, Andrew, 107, Breadalbane Terrace, Hill Street, Glasgow, General Manager and Chemist.
- Chase, R. L., 155, East Main Street, North Adams, Mass., U.S.A., Professor of Chemistry.
- Chatard, Dr. T. M., 1711, Rhode Island Avenue, Washington, D.C., U.S.A., Chemical Engineer.
- Cheney, J. P., c/o Cheney Bros., South Manchester, Conn., U.S.A., Silk Manufacturer's Chemist.
- Cheyne, A. M., c/o Messrs. Burgoyne, 16, Coleman St., E.C., Analytical Chemist.
- Cholerton, A. F., Lyndum House, Lincoln Street, Leicester, Manufacturing Chemist.
- Chope, J. A., The Laboratory, Somerset House, London, W.C., Assistant Chemist.
- Chorley, Jno. C., Lodge Lane, Bewsey, Warrington, Analytical Chemist.
- Christie, J., Levenfield, Alexandria, N.B., Dyer and Printer.
- Christy, Thos., Malvern House, Sydenham, S.E.; and 25, Lime Street, London, E.C., Chemical Botanist.
- Chrystal, W. J., Shawfield Works, Rutherglen, near Glasgow, Chemical Manufacturer.
- Church, Professor A. H., F.R.S., Shelsley, Kew, Surrey, Professor of Chemistry in the Royal Academy.
- Church, Eliah D., jun., Trenton, Wayne Co., Mich., U.S.A., Soda Manufacturer.
- Clatlin, Alan, Littleton, Mass., U.S.A., Manufacturing Chemist.
- Clanahan, H. C., 88, King Street, Manchester, Chemical Merchant.
- Clapp, Ralph R., c/o Standard Ammonia Co., Ltd., Iceland Wharf, Old Ford, E., Ammonia Works Manager.
- Clapperton, J., jun., c/o British Aluminium Co., Ltd., Larne Harbour, Co. Antrim, Ireland, Analytical Chemist.
- Clark, Donald, Bairnsdale, Victoria, Australia, Director of School of Mines.
- Clark, Edwin S., Oak Alyn, Gwersyllt, near Wrexham, Colliery Proprietor.
- Clark, Dr. J., 138, Bath Street, Glasgow, Analytical Chemist.
- Clark, R. Ingham, 3, Albert Hall Mansions, Kensington Gore, W., Manufacturer.
- Clarke, Arthur, St. Ann's Hill Factory, Nottingham, Bleacher and Dyer.
- Clarke, C. Goddard, Ingleside, Elm Grove, Peckham, S.E., Drysalter.
- Clarke, E. Lloyd, Brooklands, Cuddington, Northwich, Merchant.
- Claudet, A. C., 6, Coleman Street, London, E.C.; and (Journals to) 9, Daleham Gardens, Hampstead, N.W., Metallurgist.
- Claudet, F. G., 6, Coleman Street, E.C.; and (Journals) 3, Manor Rise Terrace, Dulwich, S.E., Assayer and Metallurgist.
- Claus, C., 9, Oxford Road, Gunnersbury, W., Chemical Engineer.
- Claus, Carl F., jun., 94, Grove Park Terrace, Chiswick, W., Electrolytic Chemist.
- Claus, Wm. H., 31, Mauldeth Road, Withington, Manchester, Manufacturing Chemist.
- Clayton, E. G., Chemical Laboratory, 32, Holborn Viaduct, London, E.C., Analytical Chemist.
- Clayton, Dr. G. Christopher, Standfield, Wavertree, Liverpool.
- Clayton, J. W., Bentfield, Alma Road, Aigburth, Liverpool, Pharmaceutical Chemist.
- Clayton, Robt. H., 61, Higher Ardwick, Manchester, Chemist.
- Clementson, H., c/o Columbus Distilling Co., 80, Pine Street, New York, U.S.A., Distiller.
- Clemes, J. H., Chyan-Bryn, Newquay, North Cornwall.

- Chemshaw, E., Alkali Works, Oldbury, near Birmingham, Technical Chemist.
- Clemons, G. H., Cudbear Street, Haunslet Road, Leeds, Dyeware Manufacturer.
- Clelland, J. E., c/o C. A. Dobson, Mills Building, New York, U.S.A., Analytical Chemist.
- Clark, Dugald, 18, Southampton Buildings, Chancery Lane, W.C., Engineer.
- Cliff, J., Nesbit Hall, Fulneck, Leeds, Firebrick Maker.
- Cliff, Stephen, Wortley, near Leeds, Firebrick Maker.
- Clifton, C. D., Royal Oak Brewery, Stockport, Brewer.
- Clegh, Jno. W., Earfield House, Douglas, Isle of Man, Brewer.
- Cloud, T. C., Wallaroo Smelting Works, Wallaroo, South Australia, Metallurgist and Manager.
- Cloves, Dr. F., University College, Nottingham, Professor of Chemistry.
- Cloves, G. A., Needham Market, Suffolk, Brewer and Malster.
- Clinton, J. H., Goring Villas, Barry Port, R.S.O., Carmarthenshire, Assayer.
- Coats, Jno. T., 91, Broughton Street, Edinburgh, Manufacturing Chemist.
- Cobb, Jno. W., Farnley Iron Co., near Leeds, Ironworks Chemist.
- Cobleigh, W. M., Bozeman, Mont., U.S.A., Assistant Chemist (State College of Agriculture).
- Coblentz, Dr. Virgil, College of Pharmacy, 115, West 68th Street, New York, U.S.A., Chemical Lecturer.
- Cochrane, Chas., Green Royde, Pelmore, near Stourbridge, Ironmaster.
- Cochrane, Jno., Spring Field, New Mills, near Stockport, Printworks.
- Coghill, P. de G., Borax Works, Old Swan, Liverpool, Technical Chemist.
- Cogswell, W. B., Syracuse, New York, U.S.A., Chemical Engineer.
- Cohen, Dr. J., York-shire College, Leeds, Analytical Chemist.
- Cohn, Alfred J., 2, East 107th Street, New York City, U.S.A., Chemist.
- Coker, Ernest G., H.M. Patent Office, Chancery Lane, W.C., Examiner of Patents.
- Colby, Albert L., c/o Bethlehem Iron Co., South Bethlehem, Pa., U.S.A., Metallurgical Engineer.
- Colby, W. H., Carrageven, Aberystwith, Analytical Chemist.
- Colchester, G. H., Burwell, near Cambridge, Manure Manufacturer.
- Colfax, Dr. Arthur, (Journals) 26, Ashgrove, Bradford, Yorks, and (notices and subs.) 14, Chester Terrace, London, S.W., Barrister-at-Law.
- Coleman, Jas. B., South-Western Polytechnic, Manresa Road, Chelsea, S.W., Analytical Chemist.
- Coleman, W. H., 9, Lloyd Road, East Ham, Essex, Tar Works Chemist.
- Collens, E., Vinegar Works, Stourport, Worcestershire, Vinegar Works Manager.
- Collett, J. M., Guy's Cliff, Wotton, Gloucester, Chemical Manufacturer.
- Collin, Dr. C. A., Ferguslie Threadworks, Paisley, N.B., Textile Chemist.
- Collins, H. S., c/o Davy, Yates, and Hicks, 64, Park Street, Southwark, S.E., Analytical Chemist.
- Collins, J. H., 14—15, Broad Street Avenue, London, E.C., Technical Chemist.
- Collins, W., Hepworth, Bradford Buildings, Bolton, Lancashire, Analytical Chemist.
- Collins, C. S. A., c/o Mrs. Goulding, 70, Elm Row, Leith Walk, Edinburgh, Chemist.
- Coleman, Dr. H. G., 23, Stirling Road, Edgbaston, Birmingham, Analytical Chemist.
- Colquhoun, D., Manlesbank, Carnoustie, N.B., Chemical Works Manager.
- Colquhoun, Lewis, c/o Nobel's Explosives Co., Ltd., Perranporth, R.S.O., Cornwall, Analytical Chemist.
- Colquhoun, W., c/o Francis Morton and Co., Lim., Garston, Liverpool, Engineer.
- Colson, A., Gas Office, Millstone Lane, Leicester, Gas Engineer.
- Comer, H., 1, Broadway, New York, U.S.A., Creosote Works Manager.
- Connor, C. C., M.P., 4, Queen's Elms, Belfast, Ireland, Chemist.
- Conradson, Pontus H., Galena Oilworks, Franklin, Pa., U.S.A., Analytical Chemist.
- Couroy, Dr. Jas. T., Woodstock, New Brighton, Cheshire, Chemist.
- Constable, W. H., The Beeches, Seabank Road, Liscard, Cheshire, Analytical Chemist.
- Coode, J. Charles, 19, Freeland Road, Ealing, W., Civil Engineer.
- Cook, E. M., Room 819, 150, Nassau Street, New York, U.S.A., Chemical Manufacturer.
- Cook, E. Rider, East London Soap Works, Bow, London, E., Soap Manufacturer.
- Cook, H. J., East London Soap Works, Bow, London, E., Soap Manufacturer.
- Cook, Jas. Williams, London and Provincial Dyeworks, Hackney Wick, N.E., Dyer.
- Cook, Jno. J., Atlas Foundry, St. Helens, Lancashire, Iron-founder.
- Cook, Wm. Martyn, 29, Highbury Hill, London, N., Analytical Chemist.
- Cooke, Arthur W., c/o W. Bettel, Box 647, Johannesburg, S.A.R., Analytical Chemist.
- Cookson, Jas. H., Stanley, near Wakefield, Alum Manufacturer.
- Cookson, N. T., Newcastle-on-Tyne, White Lead Manufacturer.
- Coomber, Thos., 40, Clarendon Road, Redland, Bristol, Chemical Lecturer.
- Cooper, A., North-Eastern Steel Co., Middlesbrough-on-Tees; and (Journals) Erdely, Middlesbrough, Steel Works Manager.
- Cooper, Bertwin, Derby Oxide and Colour Co., Lint., Rugeley, Staffordshire, Colour Manufacturer.
- Cooper, Harry J., Drinagh, Wexford, Ireland, Cement Manufacturer.
- Cooper, Walter J., c/o South Wales Cement Co., Penarth, Cardiff, Cement Works Manager.
- Corbould, Wm. H., c/o Bank of British North America, Rossland, British Columbia, Mining Engineer.
- Corcoran, Bryan, 31, Mark Lane, London, E.C., Chemical Engineer.
- Corder-James, J. H., Finsbury House, Blomfield Street, London, E.C., Mining Engineer.
- Cornett, Jas. P., Ford Paper Works, Hylton, near Sunderland, Paper Maker.
- Cornish, Vaughan, 102, Edgware Road, London, W., Chemical Lecturer.
- Corpataux, J., 6, Cliff Villas, Toller Lane, Bradford, Yorks., Technical Chemist.
- Corrie, David, c/o Nobel's Explosives Co., Ltd., Polmont Station, N.B., Technical Chemist.
- Coste, J. H., 40, Craven Street, W.C.; and (Journals) 206, Amburst Road, Hackney, E., Analytical Chemist.
- Cotterill, Thos., The Poplars, West Bromwich, Chemical Agent.
- Cotton, W. F., Hollywood Roebuck, Co. Dublin, Gas Works Manager.
- Court, Heywood, 67, Surrey Street, Sheffield, Analytical Chemist.
- Cousins, W. J., 11 and 12, Southampton Buildings, Chancery Lane, W.C., Consulting Chemist and Director.
- Cowan, W. J., 7, Park Avenue, Wood Green, N., Fine Colour Manufacturer.
- Coward, Percy, 68, Brundrett's Road, Chorlton-cum-Hardy, Manchester, Chemist.
- Cowburn, W. H., Sutton House, Ashley Road, Bowdon, Cheshire, Chemical Merchant.
- Cowley, A. J., 13, Fenchurch Avenue, London, E.C., Analytical Chemist.
- Cowper-Coles, Sherard Osborn, 39, Victoria Street, Westminster, S.W., Metallurgical Manufacturer.
- Cox, Robt., M.P., Messrs. J. and G. Cox, Gorgie, Edinburgh, Gelatine Manufacturer.
- Crabb, W., Border Counties Chemical and Manure Works, Silloth, Cumberland, Chemical Manufacturer.

Craig, G., 9, Hampden Terrace, Mount Florida, Glasgow, Technical Chemist.

Craig, Thos. J., c/o Messrs. Peter Spence and Sons, Manchester Alum Works, Manchester, Chemist.

Crake, Wm., 99, Selborne Street, Attercliffe, Sheffield, Analytical Chemist.

Craven, Chas. E., Hawthorne Cottage, White Cote Hill, Bramley, near Leeds, Dyer.

Craven, Jno., jun., Smedley Lodge, Cheetham, Manchester, Chemist.

Craw, John, 15, Cadogan Street, Glasgow, Drysalter.

Crawford, Alex., 113, Fenchurch Street, London, E.C., Chemical Merchant.

Crawford, D., Langdale's Chemical Manure Co., Ltd., St. Laurence, Newcastle-on-Tyne, Manager.

Crawford, D., The Elms, Handforth, Cheshire, Dyer and Printer.

Crawley, Arthur H., 27, Chatsworth Avenue, Aintree, Liverpool, Analytical Chemist.

Crawshaw, E., 25, Tollington Park, London, N., Dye Merchant.

Cremor, John H., 24, Superior Street, Cleveland, Ohio, U.S.A., Chemist and Metallurgist.

Cresswell, C. G., Ermyngarth, Ashted, Surrey; and 9, Bridge Street, Westminster, S.W., Chemist.

Cresswell, C. N., 1, Hare Court, Temple, E.C., Barrister-at-Law.

Crichton, Donald G. (Journals), Nundle, via Tamworth, New South Wales; (subs.) Logan Bank, Cupar Fife, N.B., Analytical Chemist.

Criper, Wm. R., Cossipore Chemical Works, Cossipore, Calcutta, India, Manufacturing Chemist.

Critchley, C. A., Victoria Works, St. Helens, Lancashire, Colour Manufacturer.

Crompton, Percy R., Elton Paper Mills, near Bury, Lancashire, Paper Maker.

Cronquist, Prof. A., Werner, Royal Wharf, Skeppsholmen, Stockholm, Sweden, Technical Chemist.

Crookes, W., F.R.S., 7, Kensington Park Gardens, Notting Hill, London, W., Analytical Chemist.

Crosby, Thos., c/o W. D. Houghton, Sankey Wire Mills, Warrington, Metallurgist.

Crosfield, A. L., 46, Bidston Road, Birkenhead, Analytical Chemist and Assayer.

Crosfield, George R., Walton Lea, Warrington, Soap Manufacturer.

Cross, C. F., 4, New Court, Lincoln's Inn, London, W.C., Analytical Chemist.

Crossley, Dr. Arthur W., Chemical Laboratory, St. Thomas' Hospital, London, S.E., Organic Chemist.

Crossley, Atkinson, The Searlet Ferrie Oxide Co., Talywain, near Pontypool, Chemist.

Crossman, Tom, Albion Brewery, Coldhurst Street, Oldham, Brewing Chemist.

Crow, Dr. J. K., 23, Vanburgh Hill, Blackheath, S.E., Technical Chemist.

Crow, Henry W., Abbey Creek Wharf, West Ham, E., Tar Distiller.

Crowder, Hedley D., The Lodge, Grove Park, Chiswick, W., Student (R.S.M.).

Crowder, W., 271, Evering Road, Upper Clapton, London, N., Manure Works Manager.

Crowther, Edw., Woodland Dyeworks, Headingley, Leeds, Dyer.

Crowther, Horace W., 21, Beeches Road, West Bromwich, Technical Chemist.

Crowther, W. M., Field House, Gomersal, near Leeds, Manufacturing Chemist.

Crumbie, W. D., 146, Washington Street, East Orange, N.J., U.S.A., Analytical Chemist.

Cubley, G. A., c/o Harrington Bros., Oliver's Yard, 53A, City Road, E.C., Chemist.

Cullen, Wm., Ardeer Terrace, Stevenston, Ayrshire, N.B., Chemist.

Cuming, James, jun., Chemical Works, Yarraville, Melbourne, Australia, Manure Manufacturer.

Cunliffe, E. T., The Parsonage, Handforth, near Manchester.

Cunliffe, Jos., Kern Mill, Whittle-le-Woods, near Chorley, Lancashire, Calico Printer.

Cunningham, Edw., Milton, Mass., U.S.A., Chemical Engineer.

Curpley, W. S., 15, Bute Mansions, Hillhead, Glasgow, Alkali Works Inspector.

Currie, Stanley C. C., 15, Broadway, New York, U.S.A., Electrical Engineer.

Curry, W. A., Giltbrook Chemical Works, Apsworth, Notts, Manager.

Cushman, Allerton S., Prescott Hall, Cambridge, Mass., U.S.A., Instructor in Chemistry.

Cuthbert, R. M., 27A, Ashley Place, London, S.W., Russia Broker.

Cuthbertson, Sir J. N., 29, Bath Street, Glasgow, Chemical Broker.

## D

Dacie, J. C., Soap Works, Putney, London, S.W., Soap Manufacturer.

Dale, Jas., The Towers, Wallington, Surrey, Coppersmith.

Dale, R. S., 1, Chester Terrace, Chester Road, Manchester, Chemical Manufacturer.

Daniell, Louis C. (Journals), Royal Standard Brewery, Tamworth, New South Wales; and (subs.) c/o W. T. Allen & Co., 132, Queen Victoria Street, London, E.C., Brewer.

Darby, J. H., Pen-y-Garth, near Wrexham, Ironmaster.

Darling, G. A., c/o Robinson Gold Mining Co., Box 1024, Johannesburg, S.A.R., Metallurgical Chemist.

Darling, W. H., 126, Oxford Street, Manchester, Analytical Chemist.

Davenport, Dr. B. F., 161, Tremont Street, Boston, Mass., U.S.A., Consulting, Sanitary, and Toxicological Chemist.

Davidson, J. E., 40, Percy Gardens, Tynemouth, Chemical Manufacturer.

Davidson, Richard, 40, Lilybank Road, Dundee, Oil Merchant's Clerk.

Davidson, R. H., c/o United Alkali Co., Ltd., Golding Davis Works, Widnes, Analytical Chemist.

Davies, G. W., 8, Spring Hill, Stockport, Chemical Lecturer.

Davies, Llewellyn J., Bute Chambers, Bute Road, Cardiff, Assistant Analyst.

Davies, M. Lloyd, Stanley Villas, Runcorn, Alkali Works Manager.

Davies, W. E., c/o Messrs. Easton, Anderson, and Goolden, Ltd., Erith, Kent, Secretary.

Davis, A. R., Lynton, Wellington Road North, Stockport, Analytical Chemist.

Davis, Chas., 3, Leitrim Terrace, High Street, East Ham, E., Analytical Chemist.

Davis, Fred., 51, Imperial Buildings, Ludgate Circus, E.C., Analytical and Consulting Chemist.

Davis, George E., Sandilands, Knutsford, Cheshire, Chemical Engineer.

Davis, Herbert J., 65, Wall Street, New York, U.S.A., Merchant.

Davis, H. W., Government Laboratory, Somerset House, W.C., Analytical Chemist.

Davis, T. Sebastian, 199, South Lambeth Road, London, S.E., Vinegar Works Chemist.

Davis, W. Walley, jun., c/o Crozer Iron Co., Roanoke, Va., U.S.A., Analytical Chemist.

Dawson, B., York House, Malvern Link, Worcestershire, Engineer.

Dawson, C. A., Holly Bank, Frodsham, Cheshire, Technical Chemist.

Dawson, Geo., Reddish Chemical Works, near Stockport, Technical Chemist.

Dawson, Jas., 27, St. Vincent Place, Glasgow; and (Journals) Eglinton Dyewood Mills, Alloa, N.B., Drysalter.

Dawson, W. Haywood, British Alizarin Co., Limited, Silvertown, Victoria Dock, E.; and (Journals), 135, Herbert Road, Woolwich, S.E., Technical Chemist.

- Deacon, H. W., 8, Ullet Road, Liverpool, Alkali Manufacturer.
- Deakin, E. C., Ryecroft House, Belmont, near Bolton. Dyer.
- Deakin, H., Ryecroft Dyeworks, Belmont, near Bolton. Dyer.
- Dearden, Thos., 12, Heywood Street, Bury, Lancashire. Technical Chemist.
- Deaville, B., Hlyson Green Works, Nottingham, Manufacturing Chemist.
- De Clerck, Maurice, Henle-lez-Courtrai, Belgium.
- Deering, W. H., Chemical Department, Royal Arsenal, Woolwich, S.E.; and (Journals) 9, Harvey Villas, Hervey Road, Blackheath, S.E., Analytical Chemist.
- Delahaye, Philibert, 65, Rue de Provence, Paris, Gas Engineer.
- De Lessing, G. C., 589, Lexington Avenue, New York, U.S.A., Manufacturing Chemist.
- Dempsey, Geo. C., 165, Market Street, Lowell, Mass., U.S.A., Chemist.
- Demuth, Dr. L., Wharfside, Church Road, Edgbaston, Birmingham, Tar Distiller.
- Denison, Joseph R., 1, Park View Terrace, Manningham, Bradford, Analytical Chemist.
- Derriek, Wm. H., c/o The Pahang Corporation Ltd., Kuantan, via Singapore, S.S., Mining Engineer.
- De Velling, F. W., Higher Grade Board School, The Boulevard, Hull. Head Master and Science Lecturer.
- Devey, A. C., 43, Redcliffe Gardens, South Kensington, S.W., Bleaching Engineer.
- Dewar, Prof. J., F.R.S., Royal Institution, Albemarle Street, W. (for Journals); and 1, Scroope Terrace, Cambridge, Professor of Chemistry and Physics.
- Dewar, Jno. A., Baleraig, Seone, N.B., Distiller.
- Dewey, Fred. P., 702, 9th Street Northwest, Washington, D.C., U.S.A., Metallurgist.
- De Wilde, Prof. P., 339, Avenue Louise, Brussels, Belgium, Professor of Chemistry.
- Dey, Prop. Lall, 4, Bendon Street, Calcutta, Manufacturing Chemist.
- Dibdin, W. J., London County Council, 40, Craven Street, London, S.W.; and (Journals) Mayfield Grange Road, Sutton, Surrey, Analytical Chemist.
- Dick, A., 110, Cannon Street, London, E.C., Chemical Engineer.
- Dick, F. Burnett, 33, Wharf Road, City Road, N., Chemist.
- Dickenson, F. M., c/o Broken Hill Proprietary Co., 3, Great Winchester Street, E.C., Secretary.
- Dickerson, E. N., 15, Wall Street, New York, U.S.A., Lawyer.
- Dickinson, A. J., Neptune Tar and Chemical Works, Deptford, S.E.; and (Journals) 4, Shardeloes Road, New Cross, S.E., Tar Distiller.
- Dickson, Jno., 54, Brown Street, Broomielaw, Glasgow, Oil Merchant.

 Duxbury, Thos., 14, Grosvenor Chambers, Deansgate, Manchester, Gas Engineer.  
 Dvorkovitch, Dr. P., 6, Willow Bridge Road, Canonbury, N., Technical Chemist.  
 Dyer, Dr. B., 17, Great Tower Street, London, E.C., Analytical and Consulting Chemist.  
 Dyson, C. E., Flint, North Wales.  
 Dyson, Dr. G., Temple House, Cheetham Hill, Manchester, Analytical Chemist.  
 Dyson, H., Manufacturing Chemist.  
 Dyson, Septimus, 2, Exchange Place, Middlesbrough, Manufacturing Chemist.

## E

Earle, Vavasour, Porchester Lodge, Streatham Common, S.W., Merchant.  
 Earnshaw, Edwin, 24, Mark Lane, London, E.C., Accountant.  
 Earp, W. R., Hulton Road, Runcorn, Cheshire, Chemical Manufacturer.  
 Eastick, C. E., Martineau's Refinery, King Edward Street, Mile End New Town, Sugar Works Manager.  
 Eastick, J. J., Millaquin Refinery, Bundaberg, Queensland, Sugar Works Manager.  
 Eastlake, A. W., 17, Temperley Road, Balham, S.W., Petroleum Works Manager.  
 Eastwick, Jos. H., East Washington Lane and Stenton Avenue, Germantown, Philadelphia, Pa., U.S.A., Chemist.  
 Eastwood, Chas., Linaere Gas Works, Bootle, near Liverpool, Gas Works Manager.  
 Eddy, Harrison P., Sewage Purification Works, Worcester, Mass., U.S.A., Superintendent.  
 Ede, Henry E., 251, School Road, Crookes, Sheffield, Analytical Chemist.  
 Edge, Anthony, Readville, Mass., U.S.A., Chemist.  
 Edmunds, Dr. Lewis H., 1, Garden Court, Temple, E.C., Barrister-at-Law.  
 Edwards, Henry W., 514, Utah Avenue, Santa Monica, Cal., U.S.A., Smelting Works Manager.  
 Edwards, W. Buckland, 101, Leadenhall Street, London, E.C., Analyst.  
 Ehrenfeld, Prof. Chas. H., York Collegiate Institute, York, Pa., U.S.A., Professor of Chemistry.  
 Ehrhardt, Ernest F., Badische Anilin und Soda Fabrik, Ludwigshafen a/Rhein, Germany, Research Chemist.  
 Ekenberg, Dr. Martin, 3, Agnegatan, Stockholm, Sweden, Technical Chemist.  
 Ekman, C. D., Paper Mills, Northfleet, Kent, Technical Chemist.  
 Elborough, T., 59, Mark Lane, London, E.C., Manure Manufacturer.  
 Elliot, John, Free Library, Wolverhampton, Librarian.  
 Elliott, Dr. A. H., Consolidated Gas Co., 4, Irving Place, New York, U.S.A., Analytical Chemist.  
 Elliott, Dr. J. F., c/o Grimwade and Co., 82, Bishopsgate Street, London, E.C., Manufacturing Chemist (Sydney, N.S.W.).  
 Ellis, Alex., Victoria Terrace, South Shields, Pharmaceutical Chemist.  
 Ellis, C. J., 13, West Scotland Street, Kinning Park, Glasgow, Technical Chemist.  
 Ellis, E. Victor, 21, Castle Street, Edinburgh, Analytical Chemist.  
 Ellis, G. Beloe, 6, Westbourne Terrace, Hyde Park, W., Patent Agent.  
 Ellis, H., 112, Regent Street, Leicester, Chemical Merchant.  
 Ellis, Prof. W. Hodgson, School of Practical Science, Toronto, Canada, Professor of Applied Chemistry.

Ellison, Henry, Platt Lane, Cleekeaton, Yorks., Manufacturing Chemist.  
 Elmore, A. S., Knostrop Old Hall, Leeds, Electro-Metallurgist.  
 Elworthy, H. S., 19, Hill Road, Bandra, Bombay, India, Sugar Works Chemist.  
 Endemann, Dr. H., 23, William Street, New York City, U.S.A., Analytical Chemist.  
 Enequist, John, 592, Clinton Avenue, Brooklyn, N.Y., U.S.A., Consulting Chemist and Chemical Engineer.  
 English, Frank H., 16, Green Terrace, Padham, Lancashire, Analytical Chemist.  
 Entwisle, Edw., Woodlands, Ashton-upon-Mersey, Cheshire, Cotton Manufacturers.  
 Ermen, F., jun., Nassau Mills, Patricroft, Manchester, Dyer and Bleacher.  
 Ernst, Adolf, Oberlangenbielau, Schlesien, Germany, Chemist.  
 Erskine, J. K. (Subscriptions), 6, Laseotts Road, Wood Green, N.; and (Journals), Geo. Goch G. M. Co., Box 540, Johannesburg, S.A.R., Analytical Chemist.  
 Esiltman, A., 25, Roe Lane, Southport, Lancashire, Analytical Chemist.  
 Estcourt, C., 20, Albert Square, Manchester, Consulting Chemist.  
 Evans, Enoch, 181, Herbert Road, Small Heath, Birmingham, Accountant.  
 Evans, Sir John, K.C.B., F.R.S., Nash Mills, Hemel Hempstead, Herts., Paper Maker.  
 Evans, Jno., H., 71, Lambton Road, Cottenham Park, Wimbledon, Analytical Chemist.  
 Evans, R. E., 3, Glencoe, Stratford-on-Avon, Brewing Chemist.  
 Evans, Dr. Thos., c/o American Cotton Oil Co., 16, Cedar Street, New York, U.S.A., Chief Chemist.  
 Evershed, F., Atlas Works, Hackney Wick, London, E., Colour Chemist.  
 Evershed, Henry G., Soap Works, Foundry Street, Brighton, Soap Maker.  
 Evershed, Wallis, c/o Whitwell & Co., Ltd., Kendal, Westmoreland, Brewer's Chemist.  
 Ewan, Dr. Thos., 20 High Street, Smethwick, near Birmingham, Chemist (Aluminium Co.).  
 Ewen, Eric D., Port of Spain, Trinidad, B.W.I., Chemist.  
 Exley, Arthur, Meanwood Grove, Meanwood, near Leeds, Tanner.

## F

Fahlberg, Dr. C., Saccharin fabrik, Salbke-Westerhüsen a/Elbe, Germany, Manufacturing Chemist.  
 Fairchild, Sam W., Kiug's Bridge, N.Y., U.S.A., Manufacturing Chemist.  
 Fairley, T., 17, East Parade, Leeds, Analytical Chemist.  
 Fairlie, H. C., 2, University Gardens, Glasgow, Chemical Manufacturer.  
 Fairweather, Wallace, 62, St. Vincent Street, Glasgow, Patent Agent.  
 Fallon, J. H. M., Casilla 232, Lima, Peru, Analytical Chemist.  
 Fanta, F., Effingham House, Arundel Street, Strand, W.C., Engineer.  
 Farrant, N., c/o J. Nicholson and Sons, Chemical Works, Hunslet, Leeds, Analytical and Metallurgical Chemist.  
 Farries, T., 16, Coleman Street, London, E.C., Manufacturing Chemist.  
 Farrington, T., 4, Waterloo Place, Cork, Ireland, Chemical Engineer.  
 Faulkner, F., The Laboratory, Bath Row, Birmingham, Consulting Brewer's Chemist.  
 Fawcett, Jas. H., c/o Bank of Australasia, Perth, West Australia, Metallurgist.  
 Fawcitt, C. A., Atlas Chemical Works, East Nelson Street, Glasgow, Chemical Manufacturer.  
 Feld, Walther, Chemische Fabrik, Linz a/Rhein, Germany, Chemical Works Director.  
 Ferguson, J. Hart, Loch Katrine Distillery, Camlaehie, Glasgow, Distillery Manager.

- Ferguson, Prof. A., The University, Glasgow, Professor of Chemistry.
- Fergusson, H., Prince Regent's Wharf, Victoria Docks, E., Technical Chemist.
- Ferguson, Wm. B., 3, Plowden Buildings, Temple, E.C., Barrister-at-Law.
- Ferrie, And., Roslin House, Ellesmere Park, Eccles, Manchester, Chemical Merchant.
- Fiebing, John H., 644, 28th Street, Milwaukee, Wis., U.S.A., Leather Trade Chemist.
- Field, C. H., Green Street Green, Orpington, Kent, Brewing Chemist.
- Field, E. W., The Brewery, Nottingham, Brewer.
- Field, S. E., Lewin's Mead Brewery, Bristol, Brewer.
- Field, S. S., 1, Bell Rock Villas, Mycenae Road, Westcombe Park, S.E., Manufacturing Chemist.
- Field, Wm. Eddington, 67, Sutherland Road, Armadale, Melbourne, Victoria, Analytical Chemist.
- Fielding, A., George Street, Salford, Manchester, Dry-salter.
- Filcock, P., Cumberland House, Cumberland Street, Macclesfield, Analytical Chemist.
- Findlay, T. J., c/o Messrs. Chapman and Messel, Silver-town, London, E., Technical Chemist.
- Finlay, Kirkman, c/o Milne & Co., 123, Bishopsgate Street, London, E.C., East India Merchant.
- Fischer, Albert, 75, Palmerston Buildings, London, E.C., Journalist.
- Fischesser, Alf., Lutterbach, bei Mülhausen, Alsace, Dye Manufacturer.
- Fisher, W. W., 5, St. Margaret's Road, Oxford, Chemical Lecturer.
- Fison, Jno., Messrs. Jas. Fison and Sons, Thetford, Norfolk, Chemical Manufacturer.
- Fitzbrown, G., Ditton Copper Works, Widnes, Metallurgist.
- Flammier, E., Heilbronn a. N., Würtemberg, Manufacturing Chemist.
- Flanagan, Chas. A., Hegewisch, Ill., U.S.A., Manufacturing Chemist.
- Fleisher, Saml., 25th and Hamilton Streets, Philadelphia, Pa., U.S.A., Woollen Manufacturer.
- Fleming, J. Arnold, 136, Glebe Street, Glasgow, Potter.
- Fleming, R. G., Tudhoe Ironworks, Spennymoor, co. Durham, Analytical Chemist.
- Fletcher, A. E., Delmore, Caterham, Surrey, Alkali Works Inspector.
- Fletcher, E. Lyon, Museum Street, Warrington; and (Journals) Grappenhall, near Warrington, Gas Engineer.
- Fletcher, Eli, Park House, Aked's Road, Halifax, Yorks, Master Dyer.
- Fletcher, E. Morley, 73, Victoria Road, Headingley, Leeds, Alkali Works Inspector's Assistant.
- Fletcher, F. W., Beauchamp Lodge, Enfield, Manufacturing Chemist.
- Fletcher, G., 3, East Ascent, St. Leonards-on-Sea, Mechanical Engineer.
- Fletcher, R. Jacques, North Geelong, Victoria, Manufacturing Chemist.
- Flintoff, R. J., Haxby, Crumpsall Lane, Manchester, Chemist.
- Flower, Major Lamorock (Lee Conservancy Board), 12, Finsbury Circus, E.C., Sanitary Engineer.
- Foden, Alfred, 52, Everton Valley, Everton, Liverpool, Metallurgical Chemist.
- Fogg, Chas. A., 39, Park Road, Bolton-le-Moors, Lecturer in Chemistry.
- Fogg, Jas., 11, Claude Villas, Grove Vale, East Dulwich, S.E., Sugar Chemist.
- Foord, Geo., Royal Mint, Melbourne, Victoria, Australia, Assayer.
- Forbes, J., Chemical Works, Old Ford, London, E., Manufacturing Chemist.
- Forbes, Paul R., 614, Sears Building, Boston, Mass., U.S.A., Chemist and Assayer.
- Ford, J. B., jun., c/o Michigan Alkali Co., Wyandotte, Mich., U.S.A., Secretary and Treasurer.
- Ford, Jno. Humphrey, Holyrood Glass Works, Edinburgh, Flint Glass Manufacturer.
- Ford, Jno. S., Abbey Brewery, Edinburgh, Analyst.
- Formoy, J. Arthur, Chestham, Grange Road, Sutton, Surrey, Oil Expert.
- Forrester, Albert, Ranipettai, North Arcot, Madras, India, Chemist and Distiller.
- Forrester, A. M., Port Dundas Chemical Works, 20, Canal Bank, Glasgow, Analytical Chemist.
- Forster, Ralph C., c/o Messrs. Bessler, Waechter, & Co., 18 and 19, Fenchurch Street, E.C., Chemical Merchant.
- Fort, Jas., 16, Adelphi Bank Chambers, South John Street, Liverpool, Chemical Merchant.
- Forth, Henry, Regent Street, New Basford, Nottingham, Drysalter.
- Foster, Jas., 11, St. Andrew's Drive, Pollokshields, Glasgow, Engineer.
- Foster, R. Le Neve, The Firs, North Road, Droylsden, Manchester, Manufacturing Chemist.
- Foster, Wm., Esholt House, Chapeltown, Leeds, Manufacturing Chemist.
- Foulis, Wm., 2, Montgomerie Quadrant, Kelvioside, Glasgow, Gas Engineer.
- Fowler, Gilbert J., 100, Plixton Road, Urmston, near Manchester, Chemical Demonstrator.
- Fox, A. Stanley, 23, South Road, Faversham, Kent, Chemist (Cotton Powder Co., Ltd.).
- Fox, J. Wesley, 115, Lower Thames Street, London, E.C., Salt Merchant.
- Fox, T., jun., Tonedale, Wellington, Somerset, Wool Manufacturer.
- France, G. T., Friar's Goose Works, Gateshead-on-Tyne Alkali Works Manager.
- France, H. C. D., 8, Vianage Road, Edghaston, Birmingham, Alkali Works Manager.
- Francis, E., Ivy Bank, Park Valley, Nottingham, Chemical Lecturer.
- Francis, E. G., c/o Manbré Saccarïne Co., Hammersmith, W., Glucose Works Manager.
- Francis, G. B., 38, Southwark Street, London, S.E., Wholesale Druggist.
- Francis, Wm., jun., City Laboratory, Cork Hill, Dublin, Chemist.
- Francis, W. H., 38, Southwark Street, London, S.E., Wholesale Druggist.
- Frank, Jerome W., 29, Broadway, New York, U.S.A., Chemist.
- Frankel, L. K., 1315, Marshall Street, Philadelphia, Pa., U.S.A., Chemical Demonstrator.
- Frankenburg, Isidor, Greengate Rubber Works, Salford, Manchester, India-rubber Manufacturer.
- Frankforter, Dr. G. B., University of Minnesota, Minneapolis, Minn., U.S.A., Professor of Chemistry.
- Frankland, Dr. E., F.R.S., The Yews, Reigate, Surrey, Professor of Chemistry.
- Frankland, H., Streosnall House, The Crescent, Linthorpe, Middlesbro', Analytical Chemistry.
- Frankland, Dr. P. F., F.R.S., Mason College, Birmingham, Professor of Chemistry.
- Fraser, Leslie McG., 98, Commercial Road East, London, E., Chemical Engineer.
- Fraser, W. J., 98, Commercial Road East, London, E., Mechanical Engineer.
- Free, R., The Elms, Mistley, Essex, Maltster.
- Freear, H. M., Hedgfield, Harpenden, Herts, Analytical Chemist.
- Freestone, J. W., 9, Clark's Terrace, New Ferry, Cheshire, Manufacturing Chemist.
- Frew, Dr. Wm., Laboratory, Well Park Brewery, Glasgow, Brewing Chemist.
- Fries, Dr. Harold H., 92, Reade Street, New York, U.S.A., Chemical Manufacturer.
- Friswell, R. J., 115, Darenth Road, Stamford Hill, London, N., Colour Manufacturer.
- Frost, Dr. Howard V., Arlington, Mass., U.S.A., Professor of Chemistry.
- Frost, Joe, Mold Green, Huddersfield, Manufacturing Chemist.
- Fryer, Dr. A. C., 13, Eaton Crescent, Clifton, Bristol, Alkali Works Inspector.
- Fuerst, Dr. Alex. F., c/o Wood Street Smelting Works, 30, Wood Street, London, E.C., Chemist.

Fuerst, Jos. F., 17, Philpot Lane, London, E.C., Chemical and Oil Merchant.  
 Fuerst, W. F., 2, Stone Street, New York, U.S.A., Chemical Merchant.  
 Fuller, Chas. J. P., L. and V. Railway Works, Horwich, near Bolton, Analytical Chemist.  
 Fuller, W. M. (Journals), Lawn Side, Stow Park Circus, Newport, Mon.; and (subscription) c/o Morris & Griffin, Ltd., Maindee, Newport, Mon., Chemical Manufacturer.  
 Fulton, H. B., 33, St. Dunstan's Road, West Kensington, W., Metallurgist.  
 Fulton, Robt., jun., Ardeer Factory, Stevenston, Ayrshire, N.B., Explosives Chemist.  
 Fulton-Smith, J., Nerquis, Mold, North Wales, Brewer.  
 Fyfe, Jno., 7, West George Street, Glasgow, Oil Works Director.  
 Fyson, G. A., Leagrave Road, Luton, Beds, Dyer.

## G

Gabbett, E. R., Prince Regent's Wharf, Victoria Docks, London, E., Chemical Engineer.  
 Gadsden, Capt. H. A., Chemical Merchant.  
 Gair, Wm., 125, Frederick Road, Aston, Birmingham, Analytical Chemist.  
 Gajjar, T. K., Alice Buildings, Bombay, India, Consulting Chemist.  
 Galbraith, Wm., c/o Glasgow Iron and Steel Co., Ltd., Wishaw, N.B., Technical Chemist.  
 Gall, Henry, Société d'Electrochimie, 1, Rue de Trevis, Paris, France, Technical Chemist.  
 Galt, Hugh Allen, c/o Michigan Alkali Co., Wyandotte, Mich., U.S.A., Works Manager.  
 Gamble, Col. D., Windlehurst, St. Helens, Chemical Manufacturer.  
 Gamble, D., jun., Ratonngh, Colwyn Bay, North Wales, Chemical Manufacturer.  
 Gamble, J. C., Cowley Hill, St. Helens, Chemical Manufacturer.  
 Gamble, Jas. N., The Laboratory, Procter and Gamble Co., Ivorydale, Ohio, U.S.A., Soap Manufacturer and Oil Refiner.  
 Gamble, W., Briars Hey, Rainhill, near Liverpool, Chemical Manufacturer.  
 Gane, Eustace H., 79, Ann Street, New York, U.S.A., Pharmaceutical Chemist.  
 Gans, Adolf, Farbenfabrik von L. Cassella & Co., Frankfurt o/Main, Germany, Dye Works Manager.  
 Gardair, Aimé, 51, Rue St. Ferréol, Marseilles, France, Director of Chemical Co.  
 Gardiner, H. J., 182a, Northumberland Park, Tottenham, N., Traveller.  
 Gardner, Walter M., Technical College, Bradford, Yorks., Assistant Lecturer on Dyeing.  
 Garibaldi, Joachim A., 21, Church Place, Gibraltar, Analytical Chemist.  
 Garner, D. C., Syston, Leicester, Manufacturing Chemist.  
 Garrett, F. C., Durham College of Science, Newcastle-on-Tyne, Teacher of Science.  
 Garrick, Dr. A. R., Huyton, near Liverpool, Manufacturing Chemist.  
 Garton, R. (Hill, Garton & Co.), Southampton Wharf, Battersea, S.W., Glucose Manufacturer.  
 Garton, Rd. S., c/o Wiggin and Co., Mond's Nickel Works, Smethwick, Birmingham, Chemist.  
 Gascoyne, Dr. W. J., 36, South Holliday Street, Baltimore, Md., U.S.A., Analytical Chemist.  
 Gaskell, H., jun., Clayton Lodge, Aigburth, near Liverpool, Alkali Manufacturer.  
 Gaskell, Holbrook, Woolton Wood, Liverpool, Alkali Manufacturer.  
 Gaster, Leon, 37, Maida Vale, W., Electrical Engineer.  
 Gate, Tom Erskine, Messrs. Howroyd and Oldroyd, Dewsbury, Yorks., Manufacturing Chemist.  
 Gatheral, G., 174, Soho Hill, Handsworth, Birmingham.  
 Geisenheimer, Theodor, 189, Front Street, New York City, U.S.A., Chemical and Dye Merchant.  
 Geisler, Dr. Jos. F., New York Mercantile Exchange Building, 6, Harrison Street, New York, U.S.A., Consulting Chemist.  
 Gendall, W. H. S., Gas Works, Elton, Bury, Gas Engineer.  
 Gent, Fred. A., jun., 103, North Front Street, Philadelphia, Pa., U.S.A., Chemist.  
 Georgi, Carl, 77, John Street, New York, U.S.A., Aniline Colour Importer.  
 Gerland, Dr. B. W., 4, Denmark Place, Acerington, Consulting Chemist.  
 Gibb, Thos., Hunt's Cross, Liverpool, Metallurgist.  
 Gibbins, H. B., 177, Redland Road, Bristol.  
 Gibbs, D. Cecil, 16, Finsbury Circus, London, E.C., Soap Manufacturer.  
 Gibbs, R. D., 320, Clapham Road, London, S.W., Works Manager.  
 Gibbs, W. P., Sulphite Pulp Mills, Hjerpen, Sweden, Analytical Chemist.  
 Gibbs, W. T., Buckingham, Prov. Quebec, Canada, Manufacturing Chemist.  
 Gibson, Dr. J., 20, George Square, Edinburgh, Chemical Lecturer.  
 Gibson, J. M., c/o Buckley Brick and Tile Co., Buckley, via Chester, Brick and Tile Manufacturer.  
 Gilbard, Francis, The Laboratory, 17, Great Tower Street, E.C., Analytical Chemist.  
 Gilbert, Sir Jos. H., F.R.S., Harpenden, near St. Albans, Agricultural Chemist.  
 Gilchrist, P. C., F.R.S., Frogna Bank, Finchley New Road, Hampstead, N.W., Metallurgist.  
 Gilchrist, Peter S., Blacksburg, S.C., U.S.A., Chemical Engineer.  
 Giles, W. B., 1, The Avenue, Church Road, Leyton, E., Chemical Works Manager.  
 Gill, Dr. Aug. H., Massachusetts Institute of Technology, Boston, Mass., U.S.A., Assistant Professor of Gas Analysis.  
 Gillman, Gustave, A.M.I.C.E., Ferro-carril de Murcia á Granada, Aguilas, Prov. de Murcia, Spain, Civil Engineer.  
 Gilmour, J. D., 190, Butterfiggins Road, Glasgow, Chemist.  
 Gimmingham, Edw. A., Stamford House, Northumberland Park, Tottenham, N. (Edison Swan United Electric Light Co. Lim.), Technical Adviser.  
 Girdwood, Dr. G. P., 82, University Street, Montreal, Canada, Professor of Chemistry.  
 Gladstone, Dr. J. H., F.R.S., 17, Pembroke Square, London, W., Professor of Chemistry.  
 Glaeser, F. A., Carpenter's Road, Stratford, E., Varnish Manufacturer.  
 Glaser, Chas., 412, East Lombard Street, Baltimore, Md., U.S.A., Manufacturing Chemist.  
 Glatz, Jos., Riverside Chemical Works, 485—493, Kent Avenue, Brooklyn, N.Y., U.S.A., Chemical Manufacturer.  
 Glen, Chas., Glengowan Printworks, Caldererix, N.B., Calico Printer.  
 Glen, J., jun., Glengowan Printworks, Caldererix, N.B., Calico Printer.  
 Glendinning, H., Mount House, The Hill, Sandbach, Cheshire, Technical Chemist.  
 Glendinning, Tom A., The Brewery, Leeds, Brewing Chemist.  
 Glenn, Wm., Baltimore Chrome Works, 1348, Block Street, Baltimore, Md., U.S.A., Chrome Manufacturer.  
 Glog, Robt. F., Grove Hill, Middlesbrough, Secretary.  
 Glover, G. T., Corbys, Hoylake, Cheshire, Chemical Works Manager.  
 Glover, H., East Falls, Schuylkill, Philadelphia, Pa., U.S.A., Chemical Works Superintendent.  
 Glover, John, 20, Holly Avenue, Newcastle-on-Tyne, Chemical Engineer.  
 Glover, T., Messrs. Mort, Liddell & Co., Widnes, Technical Chemist.  
 Glover, W., Elektrokemiska Aktiebolaget, Bengtsfors, Sweden, Technical Chemist.

- Goetz, Isidore, Château de Peyet, par Labastide-de-Sérour (Ariège), France, Manager of Mines.
- Goldschmidt, Dr. S. A., 43-51, Sedgwick Street, Brooklyn, N.Y., U.S.A., Chemical Manufacturer.
- Goldsmith, Byron B., 19, East 74th Street, New York, U.S.A., Vice-President (American Lead Pencil Co.).
- Goodall, Thos., Hendon Grange, Sunderland, Paper Manufacturer.
- Goodall, Walter, Alma House, Pudsey, near Leeds, Analytical Chemist.
- Goodwin, C. C., The White House, St. John's Road, Bowdon, Cheshire, Soapmaker.
- Goodwin, Dr. W. L., The School of Mining, Kingston, Canada, Professor of Chemistry.
- Goppelsroeder, Dr. F., Mulhausen, Elsass, Germany, Colour Chemist.
- Gordon, J. G., The Mannesmann Tube Co., Ltd., 110, Cannon Street, London, E.C., Steel Manufacturer.
- Gore, Dr. G., F.R.S., 67, Broad Street, Birmingham, Metallurgist.
- Gorvin, Jno. C., English Crown Spelter Works, Port Tennant, Swansea, Assayer.
- Gesage, F. H., Widnes, Alkali Manufacturer.
- Goulding, Wm. Joshua, 25, Eden Quay, Dublin, Manure Manufacturer.
- Gow, R. J., The Cedars, Hough Green, near Widnes, Metallurgical Chemist.
- Govald, W., 13, Russell Road, Kensington, W., Assayer and Metallurgist.
- Goyder, G. A., Ootalinka, Hawker's Road, Medindie, near Adelaide, South Australia, Chemist (Adelaide School of Mines).
- Grabfield, Dr. J. P., 1915, Indiana Avenue, Chicago, Ill., U.S.A., Chemist.
- Graesser, R., Cefn, near Ruidon, North Wales; and Argoed Hall, Llangollen, North Wales, Manufacturing Chemist.
- Graham, Dr. C., 23, Easton Buildings, Gower Street Station, London, N.W., Consulting Chemist.
- Graham, C. C., e/o Blundell, Spence & Co., Beverley Road, Hull, Technical Chemist.
- Graham, W. H., 377, Norwood Road, S.E., Industrial Chemist.
- Grandage, H., Calder Dye Works, Brighouse, near Leeds, Dyer.
- Gratama, Dr. W. D., Huize Kraayenburg, Ryswyk, Z.H., Holland, Professor of Chemical Technology.
- Graves, Geo. H., Fairfield Chemical Works, Bridgeport, Conn., U.S.A., Manufacturing Chemist.
- Graves, Walter G., 101, Grove Street, New Haven, Conn., U.S.A., Chemist.
- Gray, Elisha B., New Brighton, Richmond Co., N.Y., U.S.A., Oil Inspector and Chemist.
- Gray, G. Watson, Chemical Laboratory, 13, North John Street, Liverpool, Consulting Chemist and Assayer.
- Gray, Jno., Pentland Oil Works, Loanhead, N.B., Oil Works Chemist.
- Gray, Parker, Towerfield, Clarendon Road, Watford, Herts, Oil and Tallow Merchant.
- Gray, Thos., Technical College, 204, George Street, Glasgow, Lecturer in Chemistry.
- Greaves, I. A. R., Woodlands Park, Timperley, Altrincham, Brewer.
- Greaves, Wm., Powell Duffryn Steam Coal Co., Aberaman, Aberdare, South Wales, Chemical Engineer and Chemist.
- Greeff, Robt. W., 3, Eastcheap, London, E.C., Chemical Agent.
- Green, Alfred H., Oaklands, Lowton, Newton-le-Willows, Lancashire, Manufacturing Chemist.
- Green, A. G., 13, King's Drive, Heaton Moor, near Stockport, Colour Chemist.
- Green, H., Hayle Mill, Maidstone, Paper Manufacturer.
- Green, Jno. Edw., 1, Queen's Road, Urmston, near Manchester, Soap Works Manager.

- Harrison, G. H., Hagley, near Stourbridge, Firebrick Maker.
- Harrison, G. King, Hagley, near Stourbridge, Fire-clay Mine Owner.
- Harrison, J., Madore, Ballintemple, Cork, Chemical Engineer.
- Harrison, Jno., 35th and Gray's Ferry Road, Philadelphia, Pa., U.S.A., Chemical Manufacturer.
- Harrison, Prof. John B., Government Laboratory, Georgetown, British Guiana, Government Analyst.
- Harrison, M. C. C., Haverbrack, Bishop's Stortford, Herts.
- Hart, Bertram, c/o Tennants and Co., Clayton, Manchester, Analyst.
- Hart, Bertram H., The Elms, Old Charlton, S.E., Analytical Chemist.
- Hart, Dr. E., Lafayette College, Easton, Pa., U.S.A., Professor of Chemistry.
- Hart, H. W., 10, Falcon Avenue, Darwen, Lancashire, Analytical Chemist.
- Hart, P., c/o Tennants & Co., Clayton, Manchester, Technical Chemist.
- Hartford, Jas., 3, Cedar Street, New York, U.S.A., Aniline Merchant.
- Hartley, Arthur, Haslar Street Brewery, Gosport, Hants, Brewer.
- Hartley, Joseph, Ballavartyn, Santon, near Douglas, Isle of Man, Technical Chemist.
- Hartley, R. Kent, Springwood House, Chadderton, near Oldham, Chemical Works Manager.
- Hartley, Prof. W. N., F.R.S., Royal College of Science, Dublin, Professor of Chemistry.
- Hartog, Philip J., Owens College, Manchester, Analytical Chemist.
- Hartridge, Jas. Hills, Hohnwood, Hendon Manufacturing Chemist.
- Harvey, E. Feild, Omrac, St. John's, Newfoundland, Chemist.
- Harvey, Ernest W., 39, Alderbrook Road, Balham, S.W., A.R.S.M. Engineer.
- Harvey, H. C., Raglan House, Brooklands, near Manchester, Chemist.
- Harvey, Sidney, South-Eastern Laboratory, Canterbury, Analytical Chemist.
- Harvey, T. H., Cattedown, Plymouth, Chemical Manufacturer.
- Harzer, C. A., 79½, Gracechurch Street, London, E.C., Merchant.
- Hasenclever, R., Chemische Fabrik-Rhenania, Aachen, Prussia, Chemical Manufacturer.

- Hatfield, Jno. A., 89, Bridge Street, Wednesbury, Staffordshire, Analytical Chemist.
- Hathaway, Nath., New Bedford, Mass., U.S.A., Analytical Chemist.
- Hatschek, M., Heston Mills, Hounslow, Chemical Engineer.
- Hatton, Wm. P., c/o W. R. Hatton & Sons, Wormwood Scrubs, W., Starch Works Manager.
- Hauff, Julius, Urbanstrasse 56, Stuttgart, Germany, Chemical Manufacturer.
- Hawker, E. W., Adelaide Club, Adelaide, South Australia, Metallurgist.
- Hawkins, H., Eyeworth Lodge, Lyndhurst, Hants, Chemical Works Manager.
- Hawkins, J. Dawson, The El Paso Reduction Company, Gillett, Col., U.S.A., Smelting Works Manager.
- Hawliczek, Josef, 34, Linnai Lane, Sefton Park, Liverpool, Technical Chemist.
- Hay, Alex. B., Kelvinlock Chemical Works, Maryhill, Glasgow, Manufacturing Chemist.
- Haynes, David O., 106, Fulton Street (P.O. Box 1483), New York, U.S.A., Proprietor of "Pharmaceutical Era."
- Haynes, Geo., 12, Ince Avenue, Litherland, Liverpool, Gasworks Sub-Manager.
- Hays, Jos. A., c/o Chas. Roome Parmele Company, 98, William Street, New York, U.S.A., Chemist.
- Heal, Carlton, Hertford Lodge, Church End, Finchley, N., Chemical Student.
- Heap, Isaac H., 36, Caudon Terrace, Stoke-on-Trent, Pharmaceutical Chemist.
- Heap, L., Stacksteads, near Manchester, Manufacturing Chemist.
- Heape, Chas., 19, George Street, Manchester, Calico Printer.
- Heath, R. C., Myton Grange, near Warwick, Chemical Manufacturer.
- Hebden, Jno. C., 40, South Water Street, Providence, R.I., U.S.A., Works Manager and Chemist.
- Hecht, Jos., 2667, Commercial Street, Ravenswood, Ill., U.S.A., Analytical Chemist.
- Hecker, Paul, 102, Fenchurch Street, London, E.C., Chemical Merchant.
- Heckmann, C., 9, Grolitzerufer, Berlin, S.O., Germany, Chemical Apparatus Maker.
- Hedley, Armorer, Mayfield, Gosforth, Newcastle-on-Tyne, Soap Manufacturer.
- Hedley, Geo. H., 2, Croxeth Road, Prince's Park, Liverpool; and (Journals) Valdene Chemical Co., Westbank, Widnes, Chemical Manufacturer.
- Hedley, John, jun., 21, Russell Chambers, Bloomsbury, W.C., Chemical Merchant.
- Heerlein, Robert, Pennsylvania Salt Manufacturing Co., Natrona, Pa., U.S.A., Salt Works Chemist.
- Hefford, Geo., King Alfred's Grammar School, Wantage, Berks, Chemical Instructor.
- Hegner, O., 11, Billiter Square, London, E.C., Analytical and Consulting Chemist.
- Heisch, Godfrey P., 325, Clapham Road, London, S.W., Gas Engineer.
- Hellier, E. A., 111, Westbourne Avenue, Hull, Varnish Manufacturer.
- Hellon, Dr. R., 47, New Lowther Street, Whitehaven, Analytical and Consulting Chemist.
- Helm, H. J., Simonstone, Hammelton Road, Bromley, Kent, Superintending Analyst (Somerset House).
- Hemingway, H., 60, Mark Lane, London, E.C., Chemical Manufacturer.
- Hempleman, F. S., Wennington House, Wennington, Romford, Essex, Manure Manufacturer.
- Henderson, Jos., 3, Derwent Street, Norton Road, Stockton-on-Tees, Analyst.
- Henderson, Norman M., Broxburn Lodge, Broxburn, N.B., Oil Works Manager.
- Henderson, Prof. G. G., The Technical College, George Street, Glasgow, Professor of Chemistry.
- Henderson, W. F., Moorfield, Claremont Gardens, Newcastle-on-Tyne.
- Hendrichs, Frank H., Imperial Wharf, 45, Bankside, London, S.E., Chemical Merchant.
- Hendrick, Jass, Marischal College, Aberdeen, Lecturer on Agricultural Chemistry.
- Hennin, Alphonse, Monongahela Furnaces, McKeesport, Pa., U.S.A., Metallurgical Chemist.
- Henshaw, Jno., Green Lane, Brook Street, Manchester, Soap Manufacturer.
- Henshaw, Sam., Staffordshire Chemical Company, Limited, Tunstall, Stoke-on-Trent, Chemical Works Manager.
- Hepburn, J. G., Priory Works, Dartford, Kent, Leather Manufacturer.
- Herf, O., Herf & Frerichs Chemical Co., St. Louis, Mo., U.S.A., Chemical Manufacturer.
- Heriot, James, 18, Dumbiedykes Road, Edinburgh, Mineral Water Manufacturer.
- Herman, W. D., Eccleston Park, Prescot, Lancashire, Glass Works Chemist.
- Heron, J., 110, Fenchurch Street, London, E.C., Brewing Chemist.
- Herriot, Wm. Scott, 187, Osmaston Road, Derby, Sugar Works Engineer.
- Herrmann, R. W. (Herrmann, Keller & Co.), 102, Fenchurch Street, London, E.C., Chemical Merchant.
- Hersam, Ernest A., University of California, Berkeley, Cal., U.S.A., Instructor in Metallurgy.
- Herschel, Prof. A. S., F.R.S., Observatory House, Slough, Bucks, Hon. Professor of Experimental Physics.
- Herzmann, Dr. M., c/o Dr. Auerbach, 111, Salmgasse 15, Vienna, Austria, Technical Chemist.
- Hesketh, Everard, Dartford Ironworks, Dartford, Kent, Civil Engineer.
- Hess, Dr. Adolph, Oil Works, Leeds, Chemical Manufacturer.
- Hetherington, Dr. Albert E., Ammonia Soda Works, Fleetwood, Lancashire, Analytical Chemist.
- Hewitt, A. H., The Green Island Cement Co., Lim., Hong Kong, China, Engineer.
- Hewitt, Dr. D. B., Oakleigh, Northwich, Cheshire, Alkali Manufacturer.
- Hewitt, J. Theo., 11, Venner Road, Sydenham, S.E., Lecturer.
- Hewlett, John C., 40-42, Charlotte Street, Great Eastern Street, London, E.C., Manufacturing Chemist.
- Hey, Harry, Queen's Mills, Savile Town, Dewsbury, Dyer.
- Heyden, Dr. F. von, Chemische Fabrik, Radebeul, bei Dresden, Germany, Salicylic Acid Manufacturer.
- Heyl, J. Edw., 236, Great Clowes Street, Higher Broughton, Manchester, Chemical and Electrical Engineer.
- Heys, W. E., 70, Market Street, Manchester, Engineer and Patent Agent.
- Heys, Z. J., Stonehouse, Barrhead, N.B., Calico Printer.
- Heywood, J. G., 127, Sutherland Avenue, Maida Vale, London, W., Analytical Chemist.
- Heywood, J. H., Sparth Cottage, Manchester Road, Rochdale, Technical Chemist.
- Heywood, J. S., 7, Caledonian Road, King's Cross, London, N., Chemical Manufacturer.
- Hibbert, W., 14, Goldhurst Terrace, South Hampstead, N.W., Analytical Chemist.
- Hicks, Edwin F., 203, West 81st Street, New York City, U.S.A., Analytical Chemist.
- Hicks, Jas. A., c/o B. Redwood, 4, Bishopsgate Street Within, London, E.C., Analytical Chemist.
- Higgin, W. H., Hopefield, Bolton-le-Moors, Chemical Manufacturer.
- Higgins, C. L., c/o United Alkali Co., Lim., Muspratt's Works, Widnes; and (Journals) 79, Bedford Street South, Liverpool, Manufacturing Chemist.
- Hill, Frank, 52, Water Street, New York, U.S.A., Manufacturing Chemist.
- Hill, J. K., 13, Osborne Place, Copland Road, Govan, near Glasgow, Manufacturing Chemist.
- Hill, Sydney, 11, Salisbury Gardens, Westbourne Avenue, Hull, Analytical Chemist.
- Hills, C. H., Anglesea Copper Works, Low Walker, Newcastle-on-Tyne, Copper Smelter.
- Hills, Harold F., Pine Island Post Office, Kent, Auckland, New Zealand, Analytical Chemist.
- Hills, W., 223, Oxford Street, London, W., Pharmaceutical Chemist.

- Hilton, Edgar G., 37, Kourlandsky Street, St. Petersburg, Russia, Varnish and Paint Manufacturer.
- Hindle, J. H., 8, Cobham Street, Accrington, Dycworks Manager.
- Hinds, James, 127, Gosford Street, Coventry, Pharmaceutical Chemist.
- Hinman, Bertraud C., c/o Ironclad Manufacturing Co., 186, Cook Street, Brooklyn, E.D., U.S.A., Metallurgical Chemist.
- Hinshelwood, Thos., Glasgow Oil and Paint Works, Glenpark Street, Glasgow, Oil Refiner.
- Hirst, H. Reginald, 4, Marlboro' Villas, Victoria Avenue, Harrogate, Yorks, Works Chemist.
- Hislop, Geo. R., Gas Work House, Craigielea, Paisley, N.B., Gas Engineer and Manager.
- Hodge, Andrew, Dalmonach Printworks, Alexandria, N.B., Chemist.
- Hodges, Harry B., Southern Railway Co., 1300, Pennsylvania Avenue, Washington, D.C., U.S.A., Chemical Engineer.
- Hodges, J. F., 14, Alfred Street, Belfast, Analytical Chemist.
- Hodgkin, J., 12, Dynevor Road, Richmond, Surrey, Chemical Manufacturer.
- Hodgkinson, J. H., Messrs. E. Potter & Co., Dinting Vale, Glossop, Technical Chemist.
- Hodgkinson, Dr. W. R., 8, Park Villas, Blackheath, S.E. (Journals); and Royal Military Academy, Woolwich, S.E., Prof. of Chemistry.
- Hodgson, C., High House, Eppleby, Darlington, Metallurgical Chemist.
- Hodgson, Wm., 66, Deansgate, Manchester, Oil and Colour Broker.
- Hogben, W., 18, Hunter's Road, Handsworth, Birmingham, Analytical Chemist.
- Hogg, A. F., 4, Cliffe Terrace, Woodlands Road, Darlington, Teacher of Chemistry.
- Hogg, Quintin, 23, Rood Lane, London, E.C., Merchant.
- Hogg, T. W., c/o John Spencer & Sons, Newburn Steelworks, Newcastle-on-Tyne, Metallurgical Chemist.
- Holden, G. H., Langley Place, Victoria Park, Manchester, Manufacturing Chemist.
- Holgate, S. V., 29, Long Row, Nottingham, Pharmaceutical Chemist.
- Holgate, T. E., 146, Blackburn Road, Darwen, Lancashire, Metallurgist.
- Holgate, T., 12, Hyde Park Road, Halifax, Gas Engineer.
- Holland, Jos., 70, Higher Ardwick, Manchester, Brewer.
- Holland, Philip, 22, Tavito Street, Gordon Square, London, W.C., Analytical Chemist.
- Holland, Philip H., 958, Sherbrooke Street, Montreal, Canada, Merchant.
- Holliday, R. (Read, Holliday & Sons), Huddersfield, Dye Manufacturer.
- Holliday, Thos., Lunelough Hall, Huddersfield, Aniline Dye Manufacturer.
- Hollings, J. Spencer, Brymbo, North Wales, Works Manager.
- Holloman, Fred R., c/o Tennant's Agency, San Fernando, Trinidad, W.I., Sugar Works Chemist.
- Holloway, G. T., 57 and 58, Chancery Lane, W.C., Analytical and Consulting Chemist.
- Holloway, Wm., Newlands, Middlesbro', Manufacturing Chemist.
- Holmes, Ellwood, 3, Fenwick Terrace, Jesmond, Newcastle-on-Tyne, Colour Manufacturer.
- Holmes, F. G., Ambleside, Harehills Avenue, Leeds, Technical Chemist.
- Holmes, J., 96, Holland Road, Brixton, London, S.W., Analytical Chemist.
- Holt, J. W., North Road, Clayton, near Manchester, Chemical Works Manager.
- Holton, E. C., Sherwin-Williams Co., 100, Canal Street, Cleveland, Ohio, U.S.A., Chemist.
- Holzappel, Max., Quayside, Newcastle-on-Tyne, Manufacturer.
- Homfray, D., 6, Dartmouth Row, Greenwich, S.E., Analytical Chemist.
- Hooker, Benj., Pear Tree Court, Farringdon Road, London, E.C., Mechanical Engineer.
- Hooper, E. G., The Laboratory, Somerset House, London, W.C., Analytical Chemist.
- Hooper, Ernest F., Wear Fuel Works, Hendon Dock, Sunderland, Technical Chemist.
- Hope, Jas., The Nickel Co., Kirkintilloch, N.B., Nickel Works Manager.
- Hopkin, W. K., Fernbrae, Brondesbury Park, N.W., Chemical Manufacturer.
- Hopkins, Erastus, 12, Linden Street, Worcester, Mass., U.S.A., Chemist.
- Hopkins, Gerald V., Nicholaston House, Penmaen, near Swansea, Metallurgist.
- Hopkins, Herbert W., 13, Harrington Gardens, South Kensington, S.W., Metallurgist.
- Hopkinson, John, Marion Street, Lister Hills, Bradford, Yorks, Lubricant Manufacturer.
- Horn, Wm., Lautaro Nitrate Co., Taltal, Chili, Technical Chemist.
- Horn, W. Freeman, Wandle Colour Works, South Street, Wandsworth, S.W., Varnish, Paint, and Printing Ink Manufacturer.
- Horne, W. D., Youkers, N.Y., U.S.A., Consulting Chemist.
- Horrocks, W. A., 5, Egerton Avenue, Urnston, near Manchester, Bleacher and Finisher.
- Horsman, Fred., 78, Ham Park Road, Forest Gate, Essex, Chemist.
- Horton, William, 38, Belvidere Road, Prince's Park, Liverpool, Analytical Chemist.
- Hosie, G. H., Davidson Place, Inverell, Argyllshire, Technical Chemist.
- Hoskins, A. Percy, 25, Cromwell Road, Belfast, Analytical Chemist.
- Hotson, Arthur E., 1 and 3, Union Square, New York City, U.S.A., Chemist.
- Houston, John, 14, Charlotte Street, Manchester, Dry-salter.
- Honston, Robt. S., Hawkhead Road, Paisley, N.B., Analytical Chemist.
- Hovenden, Fred., Glenlea, Thurlow Park Road, West Dulwich, S.E.
- Howard, A. G., Holmbury, Woodford, Essex, Chemical Manufacturer.
- Howard, D., Devon House, Buckhurst Hill, Essex, Chemical Manufacturer.
- Howard, D. L., City Mills, Stratford, London, E., Chemical Manufacturer.
- Howard, W. D., City Mills, Stratford, London, E., Chemical Manufacturer.
- Howorth, Franklin W., c/o Lloyd Wise, 46, Lincoln's Inn Fields, W.C., Manufacturing Chemist.
- Hoyte, Percy S., Gas Works, Cosside, Plymouth, Gas Engineer.
- Hudson, Jos., Rawden Lodge, Headingley, Leeds, Drysalter.

 Iriye, Koremasa, China and Japan Trading Co., Kobe, Japan, Analytical Chemist.  
 Irvine, R., Royston, Granton, Edinburgh, Chemical Manufacturer.  
 Irving, J. M., 17A, Dickinson Street, Cooper Street, Manchester, Chemical Merchant.  
 Irwin, W., 3, Wilton Polygon, Cheetham Hill, Manchester, Analytical Chemist.  
 Isaac, J. F. V., 114, Marine Parade, Brighton, Research Chemist.  
 Isaac, T. W., Player, 114, Marine Parade, Brighton, Chairman of Water Works Co.  
 Isaacs, Louis A., 180, Belsize Road, West Hampstead, N.W., Manufacturer.  
 Isler, Otto, 35-37, Dickinson Street, Manchester, Chemical Merchant.  
 Ivatts, Harold E., 27, Wellington Square, Chelsea, S.W., Analytical Chemist.

## J

Jackman, E. J., 60, Belgrave Road, Ilford, Essex, Technical Chemist.  
 Jackson, Edgar, 106, Queen Victoria Street, London, E.C., Analytical and Consulting Chemist.  
 Jackson, Edward, Ashleigh, Beaufort Road, Edgbaston, Birmingham, Alkali Works Inspector.  
 Jackson, F., Spring Bank, Crumpsall Lane, Manchester, Chemical Apparatus Maker.  
 Jackson, Frederick, 10, Half Moon Street, Manchester, Laboratory Furnisher.  
 Jackson, G. B., 6, Booth Street, Piccadilly, Manchester, Chemical Manufacturer.  
 Jackson, John, 98, Dobbie's Loan, Glasgow, Lubricant Manufacturer.  
 Jackson, R. V., c/o Scotch and Irish Oxygen Co., Polmadie, Glasgow, Technical Chemist.  
 Jackson, Robt., 18, Harrington Street, Dublin, Analytical Chemist.  
 Jackson, Saml., c/o Messrs. Binny & Co., Madras, India, Analytical Chemist.  
 Jackson, T., Clayton, near Manchester, Chemical Manufacturer.  
 Jackson, Walter, 24, Sydenham Avenue, Sefton Park, Liverpool, Metallurgical Chemist.  
 Jackson, Rt. Hon. W. L., M.P., F.R.S., 27, Cadogan Square, S.W.; and (Journals) Allerton Hall, Chapel Allerton, near Leeds, Leather Manufacturer.  
 Jackson, W. P., Saxilby, near Lincoln, Chemical Works Manager.  
 Jago, Wm., Godfrey House, Wilbury Avenue, Hove, Brighton, Chemical Engineer.  
 James, Alf., Cassel Gold Extracting Co., 108A, Hope Street, Glasgow, Mining Engineer.  
 James, E. T., British Alizarin Co., Ltd., Silvertown, Victoria Docks, E., Secretary.  
 James, J. Herniman, Assay Office, Swansea, Assayer.  
 James, Dr. J. Wm., Aylmer House, Weston-super-Mare; and (Journals) 29, Redcliff Street, Bristol, Chemical Lecturer.  
 James, Lawrence S., 32, Hawley Street, Boston, Mass., U.S.A., Gas Inspector.  
 Jameson, A. H., Cleveland Linseed Oil Co., South Chicago, Ill., U.S.A., Chemist.  
 Jantzen, Paul, 132, Fenchurch Street, London, E.C., Chemical Merchant.  
 Japp, Dr. F. R., F.R.S., The University, Aberdeen, Professor of Chemistry.  
 Jarmain, Geo. S., Minerva Works, Turnbridge, Huddersfield, Wool Extractor.  
 Jarmay, G., Hartford Lodge, Hartford, Cheshire, Alkali Manufacturer.  
 Jarrett, H. T., 90, William Street, New York, U.S.A., Chemist.  
 Jarvis, Deming, Michigan Carbon Works, Detroit, Mich., U.S.A., Manufacturing Chemist.  
 Jarvis, Talbot McL., c/o Ind., Coope, and Co., Ltd., Burton-on-Trent, Brewer.  
 Jayne, Dr. H. W., 931, North Broad Street, Philadelphia, U.S.A., Manufacturing Chemist.  
 Jekyll, J., Castle Moat House, Lincoln, Chemical Manufacturer.  
 Jenkin, W. A., 24, Bella Vista, Minas de Rio Tinto, Provincia de Huelva, Spain, Metallurgical Chemist.  
 Jenkins, John H. B., Laboratory, G.E.R. Works, Stratford, E., Analytical Chemist.  
 Jenkins, Thos., Bella Vista, Port Talbot, South Wales, Technical Chemist.  
 Jenkins, Thos. H., 5, Bellott Street, Cheetham, Manchester, Analytical Chemist.  
 Jenks, Robt. L., Research Department, Imperial Institute, London, S.W., Chemist.  
 Jenner, E., 209, Markhouse Road, Walthamstow, Essex, Chemical Manufacturer.  
 Jennison, F. H., Craighall Chemical Works, Maryhill, Glasgow, Dyer.

- Job, Robt., 130, Franklin Street, Reading, Pa., U.S.A., Analytical Chemist.
- Johnson, A. E., 1, Eagle Villas, Penn Fields, Wolverhampton, Analytical Chemist.
- Johnson, Chas. H., jr., Laboratory, Rubberine Works, Outlands Mill, Leeds, Works Manager.
- Johnson, Edmund E., Engineering Works, Carpenter's Road, Stratford, E., Chemical Engineer.
- Johnson, J. E., 40, Idmiston Road, Stratford, London, E., Manufacturing Chemist.
- Johnson, J. Grove, 23, Cross Street, Finsbury, London, E.C., Assayer.
- Johnson, J. Henry, Mountains, Tunbridge, Kent, Patent Agent.
- Johnson, Jesse F., c/o Hamilton Powder Co., Montreal, Canada, Chemical Engineer.
- Johnson, S. H., Warren Hill House, Loughton, Essex, Chemical Engineer.
- Johnson, T. A., Field House, Winnington Park, Northwich, Cheshire.
- Johnston, Alex. R., 370, North Woodside Road, Glasgow, Analytical Chemist.
- Johnston, G. L., Kingswood Road, Sydenham Hill, S.E., Secretary.
- Johnston, Thos., Nobel's Explosives Co., Ltd., 149, West George Street, Glasgow, Explosives Co.'s Manager.
- Johnston, Wm. A., The S.S. White Dental Manufacturing Co., Princess Bay, New York, U.S.A., Dental Enamel Manufacturer.
- Johnston, Wm. E., Kingswood Road, Sydenham Hill, S.E., Assistant Chemist (Bovril, Limited).
- Johnston, Wm. G., Chemical Works, Coatbridge Street, Port Dundas, Glasgow, Technical Chemist.
- Johnston, W. G., Warwicks' and Richardsons' Brewery, Newark-on-Trent, Chemist.
- Johnstone, Jas., Shawfield Works, Rutherglen, Glasgow, Technical Chemist.
- Johnstoun-Coombes, Dr. W., 5, Cambridge Place, Falmouth, Analytical Chemist.
- Jones, A. E. Syers, Iquique, Chile, "Nitrate" Manufacturer.
- Jones, Chapman, Royal College of Science, South Kensington, S.W., Senior Demonstrator in Chemistry.
- Jones, David S., c/o The Lisbon Berlyn Co., Ltd., Pilgrim's Rest, Lydenburg, S.A.R., Analytical Chemist.
- Jones, Prof. D. E., 4, Conway Road, Cardiff, Inspector (Science and Art Department).
- Jones, E. W. T., 10, Victoria Street, Wolverhampton, Analytical Chemist.
- Jones, G. Cecil, Basingstoke Ironworks, Basingstoke, Works Chemist.
- Jones, Herbert. See Sefton-Jones, H.
- Jones, M. W., 433, Stretford Road, Old Trafford, Manchester, Analytical Chemist.
- Jones, T. Tolley, 356, Little Collins Street, Melbourne, Victoria, Explosives Manufacturer.
- Jones, W. Norris, Lancashire Metal Works, Widnes, Technical Chemist.
- Joseland, Walter H., Hall Street, Burslem, Staffordshire, Manager of Chemical Works.
- Joslin, Omar T., 505, West 157th Street, New York City, U.S.A., Chemical Engineer.
- Joüet, Dr. C. H., Roselle, Union Co., N.J., U.S.A., Technical Chemist.
- Journand, Louis, Ste. Colombe-lz-Vienne, Rhône, France, Technical Chemist.
- Joy, Douglas G., Pine Wood, Beverley, Yorks, Oil Refiner.
- Julien, Alfred, Société des Peintures Sous-marines, 17, Rue Beauvan, Marseilles, France, Civil Engineer.
- Jürgensen, Dr. Rolof, Zizkagasse, 12, Weinberge, Prague, Austria, Chemist.
- Justice, P. M., 14, Southampton Buildings, Chancery Lane, London, W.C., Patent Agent.
- Kalle, Dr. Wm., Biebrich-am-Rhein, Germany, Colour Manufacturer.
- Kathreiner, Franz, Worms a Rhein, Germany, Technical Chemist.
- Kaufmann, Dr. Herbert M., c/o Mutual Chemical Co., Jersey City, N.J., U.S.A., Chemist.
- Kawakita, Michitada, Kant Strasse 2400, Charlottenburg, Berlin, Analytical Chemist.
- Kay, H. A., 71, Maids Vale, London, W., —
- Kay, Dr. Percy, West London Polytechnic, Manresa Road, Chelsea, S.W., Analytical Chemist.
- Kay, W. E., Gowanbank, Busby, near Glasgow, Printworks Chemist.
- Kearns, H. W., Baxenden, near Acerrington, Dyer.
- Kebler, Lyman F., 305, Cherry Street, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
- Keiser, E. H., Bryn Mawr College, Bryn Mawr, Pa., U.S.A., Professor of Chemistry.
- Kellie, Jas. M., Fount Cottage, Loanhead, near Edinburgh, Technical Chemist.
- Kellner, Dr. Wm., 13, Victoria Road, Old Charlton, S.E., Chemist to War Department.
- Kempson, John F., Pye Bridge Chemical Works, near Alfreton, Derbyshire, Chemical Manufacturer.
- Kennedy, Wm., 28, Royal Exchange Square, Glasgow, Oil Works Director.
- Kenrick, Prof. Edgar B., St. John's College, Winnipeg, Manitoba, Canada, Professor of Chemistry.
- Kent, Wm. J., Holly Lodge, Horseshoe, Yorks, Assayer and Chemical Engineer.
- Kenyon, Thos., The Shrubbery, Hilton Park, Prestwich, near Manchester, Manufacturing Chemist.
- Ker, Alan D., Millburn Chemical Works, Garngad Hill, Glasgow, Chemical Manufacturer.
- Kernick, Rich. P., 104, Claude Road, Roath Park, Cardiff, Manufacturing Chemist.
- Kerr, Jas., c/o Linlithgow Oil Co., Ltd., Linlithgow, N.B., Works Chemist.
- Kerr, Saml. T., c/o Alex. Kerr Bros. & Co., Philadelphia, Pa., U.S.A., Salt Manufacturer.
- Kershaw, J., Grease, Varnish, and Cement Works, Hollinwood, near Oldham, Varnish Manufacturer.
- Kershaw, J. B. C., 73, Gloucester Street, Pimlico, S.W., Analytical Chemist.
- Kestner, Paul, 40, Boulevard Vauban, Lille, France, Chemist.
- Keys, W. H., Hall End Chemical Works, West Bromwich, Oil and Chemical Manufacturer.
- Kibble, W. Oakes, G.P.O., Auckland, New Zealand, Chemical Engineer.
- Kier, Thos., Thornliebank, Glasgow, Chemist.
- Kinch, E., Royal Agricultural College, Cirencester, Professor of Chemistry.
- King, A. J., Ingersley Vale, Bollington, near Macclesfield, Bleacher and Finisher.
- King, C. M., Wardrobe Chambers, Queen Victoria Street, E.C., Chemical Engineer.
- King, C. M., Campsie Alum Works, Leunoxtown, N.B., Alum Manufacturer.
- King, Sir James, Bart., 115, Wellington Street, Glasgow, Chemical Manufacturer.
- King, J. Falconer, Russell Place, Edinburgh, N.B., Consulting Chemist.
- King, J. T., Clayton Square, Liverpool, Patent Agent.
- King, Robt., 115, Wellington Street, Glasgow, Chemical Manufacturer.
- King, Sidney J., 49, Arundel Square, Barnsbury, N., Colour and Dyestuff Traveller.
- King, Walter R., 55, Sunderland Road, Forest Hill, S.E., Chemical Manufacturer.
- Kingdon, G. Holman, c/o Joseph Crossfield and Sons, Warrington, Technical Chemist.
- Kingsford, T. P., Oswego, New York, U.S.A., Starch Manufacturer.
- Kingzett, C. T., Elrstead Knoll, Chislehurst, Kent, Technical Chemist.
- Kinnicutt, Professor L. P., 77, Elm Street, Worcester, Mass., U.S.A., Professor of Chemistry (Worcester Polytechnic Institute).

- Kirkman, R., Landore Alkali Works, Swansea, Alkali Works Manager.
- Kirkpatrick, A. J., 179, West George Street, Glasgow, Chemical Merchant.
- Kitamura, Y. (Journals), c/o R. Fujihara, Yokoyama-cho Saehome, Tokyo, Japan, Agricultural Chemist.
- Kitchen, Theo. (Journals), 28, Flinders Lane North, Melbourne, Australia; and (subs.) 35, Queen Victoria Street, E.C., Soap and Candle Manufacturer.
- Kitson, Sir James, Bart., M.P., Gledhow Hall, Leeds, Iron and Steel Manufacturer.
- Kitto, R., 26, Lancaster Road, Finsbury Park, London, N., Analytical Chemist.
- Kleemann, Dr. S., 84, Shrewsbury Road, Old Trafford, Manchester, Analytical Chemist.
- Klipstein, A., 122, Pearl Street, New York, U.S.A. (P.O. Box 2833), Chemical Manufacturer and Importer.
- Klonowski, W. T. von, P.O. Box 64, Krugersdorp, S.A.R., Chemist and Druggist.
- Knaggs, Alfred B., Bradley Lane, Huddersfield, Technical Chemist in Dyeworks.
- Kuecht, Dr. E., Station Road, Crumpsall, Manchester, Analytical Chemist.
- Knight, A. H., 2, Gerald Road, Oxtou, Cheshire, Assayer.
- Knight, Henry, 33, Faraday Street, Breck Road, Liverpool, Colour and Varnish Manufacturer.
- Knight, J. B., Silvertown Soapworks, Silvertown, London, E., Soap Manufacturer.
- Knight, J. J., 13, Grafton Street, West Gorton, near Manchester, Technical Chemist.
- Knight, Wm. A., Sexey's Trade School, Bruton, Somerset, Head Master.
- Knights, J. West, County Laboratory, 1, Sidney Street, Cambridge, Analytical Chemist.
- Knipler, F., c/o R. Harper and Co., 352, Flinders Lane, Melbourne, Victoria, Starch Manufacturer.
- Knowles, Joshua, Stormer Hill, Tottington, near Bury, Calico Printer.
- Knox, E. W., Colonial Sugar Refining Co., Sydney, N.S.W.; and c/o Parbury Henry & Co., 7, East India Avenue, London, E.C., Sugarworks Chemist.
- Koechl, Victor, 79, Murray Street, New York, U.S.A., Dye Merchant.
- Koechlin, Horace, 19, Avenue du Mont Riboudet, Rouen, France; and (subs.) c/o Koechlin, Baumgartner and Co., 79½, Watling Street, E.C., Chemical Manufacturer.
- Kohn, Dr. Chas. A., University College, Brownlow Street, Liverpool, Chemical Demonstrator.
- Kohnstamm, E. H., 44, West Broadway, New York, U.S.A., Colour Maker and Importer.
- Kolb, J., Soc. Anon. des Manuf. de Produits Chimiques, Lille, France, Chemical Manufacturer.
- Koningh, L. de, 325, Kennington Road, S.E., Analytical Chemist.
- Kraftmeier, E., 55, Charing Cross, London, S.W., Explosives Manufacturer.
- Krause, Dr. Albert H., 63, Mueller Avenue, Cleveland, Ohio, U.S.A., Chemist (Grasselli Chemical Co.).
- Krause, Dr. G., "Chemiker-Zeitung," Cöthen, Germany, Editor.
- Krause, O. H., c/o American Sugar Refining Co., Jersey City, N.J., U.S.A., Chemical Engineer.
- Kuhl, W. H., 73, Jägerstrasse, Berlin, Germany, Bookseller.
- Kunheim, Dr. Hugo, 32, Dorathcen-strasse, Berlin, Chemical Manufacturer.
- Kupferberg, Dr. H., 303, Collyhurst Road, Manchester, Technical Chemist.
- Kuttruff, Adolf, 128, Duane Street, New York, U.S.A., Chemical Merchant.
- Kyngston, J. W., 3, Oak Terrace, Beech Street, Liverpool, Chemical Engineer.
- Lagerwall, Dr. Ivar, 3, Prince's Street, London, E.C., Petroleum Manufacturer.
- Laidler, C. P., 20, Noble Terrace, Gateshead-on-Tyne, Analytical Chemist.
- Laing, Jno., 3, Mentoue Terrace, Edinburgh, Analytical Chemist.
- Laing, Wm., 115, Swan Arcade, Bradford, Yorks, Oil Merchant.
- Lake, G., jun., 83, Primrose Lane, Glossop, Derbyshire, Analytical Chemist.
- Lambert, Alan, Union Oil Mills, Ltd., 18, Bishopsgate Street Within, E.C., Oil Mills Director.
- Lancaster, Jno. C., 12, Player Street, Alfreton Road, Nottingham, Engineering Works Manager.
- Lander, Albert H., 7, Carlyle Road, Edgbaston, Birmingham, Metal Merchant.
- Landin, John, 40, Drottninggatan, Stockholm, Sweden, Public Analyst.
- Lane, Howard, 188, Corporation Street, Birmingham, Consulting Mechanical Engineer.
- Lang, Jas. G., 5, Viewfield Terrace, Hillhead, Glasgow, Analytical Chemist.
- Langbeck, H. W., The Park, Loughton, Essex, Technical Chemist.
- Langdon, Dr. M. J., 15, Dickinson Street, Manchester, Analytical Chemist.
- Lange, Dr. Martin, Van Baerlestraat 94, Amsterdam, Holland, Analytical Chemist.
- Laugen, H. G., Maschinenfabrik Grevenbroich, Grevenbroich, Germany, Chemical Engineer.
- Langenbeck, Carl, 27, Orchard Street, Zanesville, Ohio, U.S.A., Manager (Mosaic Tile Co.).
- Langer, Dr. Carl, 29, Avenue Road, Regent's Park, N.W., Analytical Chemist.
- Langrick, Thos. E., 2, Bonnington Terrace, Edinburgh, Paint Works Manager.
- Larkin, T., St. Bede Works, Jarrow-on-Tyne, Chemical Works Manager.
- Larned, J. N., Young Men's Library, Buffalo, N.Y., U.S.A., Librarian.
- Lascelles, Jno. H., 1, Lall Bazar, Calcutta, India, Chemist.
- Lassing, Henry, M.D., 19, Park Place, New York, U.S.A., Editor and Leather Manufacturer.
- Latham, Baldwin, 13, Victoria Street, Westminster, S.W., Civil Engineer.
- Latham, J. J., 157, Albert Road, Appleton, Widnes, Chemical Works Manager.
- Lawrance, H. A., Analytical Chemist.
- Lawrence, Jas., Repauno Chemical Co., Paulsboro', N.J., U.S.A., Assistant Superintendent of Works.
- Laws, J. P., Westfield, Bath Road, Worcester, Analytical Chemist.
- Lawson, Arthur J., Marsh Soapworks, Bristol, Soap Manufacturer.
- Lawson, Dr. T. A., 114, Alexandra Road, London, N.W., Colour Chemist.
- Lawton, Thos., Calthorpe House, Aldridge Road, Perry Bar, Birmingham, Chemical Works Manager.
- Laycock, Dr. W. E., 2, Park Street, Dewsbury, Analytical Chemist.
- Leach, Walter, 22, St. Andrew's Place, Bradford, Yorks, Analytical Chemist.
- Leathart, Thos. H., Bracken Dene, Gateshead-on-Tyne, Lead Manufacturer.
- Leather, Dr. J. W., Dehra Dun, N.W.P., India, Agricultural Chemist, Government of India.
- Le Bouillier, Clement, c/o Taylor Iron and Steel Co., High Bridge, N.J., U.S.A., Chemist.
- Lecomber, W. G., Moorland Villa, Brooklands, near Manchester, Engineer.
- Lederle, Dr. E. J., Health Department, New York City, U.S.A., Chief Chemist.
- Ledoff, Prof. A., Technological Institute, Kharkoff, Russia, Professor of Chemistry.
- Ledoux, Dr. Albert R., 9, Cliff Street, New York City, U.S.A., Chemist.
- Lee, C. Tennant, 146, Franklin Street, Boston, Mass., U.S.A., Analytical Chemist.
- L
- Lacey, E. C., 10, Clarence Road, Croydon, Manufacturing Chemist.
- Lacey, T. S., Gas Light and Coke Company, Lupus Street, Pimlico, S.W., Gas Engineer.

- Lee, J. W. Richmond, 70, St. Helens Gardens, North Kensington, W., Mining Engineer.
- Lee, S. Wright, 6-10, Whitechapel, Liverpool, Wholesale Druggist.

 Macarthur, J. G., 98, Dobbie's Loan, Glasgow, Lubricant Manufacturer.  
 McArthur, J. S., Cassel Gold Extracting Co., Limited, 108A, Hope Street, Glasgow, Technical Chemist.  
 McArthur, Thos., Cairndlu, Kirklee Road, Glasgow, Drysalter and Dyewood Extractor.  
 McBretney, E. G., Pontefract Road, Castleford, Yorks, Glass Works Chemist.  
 McCallum, J. M., South Park, Paisley, N.B., Soap Manufacturer.  
 McCalman, D., Waterside, Irvine, N.B., Technical Chemist.  
 McCann, Owen, Printing Ink Manufacturer.  
 McCombie, C., c/o C. Gross and Co., 9, Mincing Lane, London, E.C., Drug and Chemical Merchant.  
 McCowan, W., 45, Mott Street, Birmingham, Brewer.  
 McCrae, Dr. John, jun., Mason College, Birmingham, Student of Chemistry.  
 McCulloch, J., Oakleigh, Rose Street, Garnet Hill, Glasgow, Chemical Works Manager.  
 McCulloch, Norman, 7, Melrose Street, Glasgow, Analytical Chemist.  
 McDaniel, J. J., Bandon, Ireland, Distiller.  
 Macdonald, A., 72, Great Clyde Street, Glasgow.  
 McDonald, John, Distillery Offices, Fort William, N.B., Distiller.  
 Macdonald, J. W., c/o Messrs. H. Tate & Sons, Love Lane, Liverpool, Analytical Chemist.  
 McDonald, T. M., Wallabo Estate, St. Vincent, West Indies, Sugar Chemist.  
 McDougall, Arthur, Fallowfield House, Fallowfield, Manchester, Chemical Manufacturer.  
 McDougall, Isaac, jun., High Bank, Didsbury, Manchester, Student.  
 McDougall, Isaac S., High Bank, Didsbury, Manchester, Manufacturing Chemist.  
 McDougall, J. T., Dunolly, Morden Road, Blackheath, S.E., Manufacturing Chemist.  
 MacEwan, Peter, 4, Gresley Road, Hornsey Lane, N. (Journals); and 42, Cannon Street, E.C.; Editor of "Chemist and Druggist."  
 McEwen, Atholl F., 43, Gilmore Road, Lewisham, S.E., and (Journals) Box 237, Rossland, British Columbia, Analytical Chemist and Assayer.  
 McEwen, Jas., Ruthven House, Bowden Lane, Marple, Cheshire, Aerated Water Engineer.  
 Macfarlane, J. A., 623, Hastings Street (Box 655), Vancouver, British Columbia, Metallurgical Chemist.  
 Macfarlane, R. F., Tharsis Copper Works, East Moors, Cardiff, Technical Chemist.  
 Macfarlane, Thos., Inland Revenue Dept., Ottawa, Canada, Analyst to Dominion of Canada.  
 Macfarlane, Walter, Kelvin, Hollies Drive, Wednesbury, Chemist and Metallurgist.  
 McFarlane, Walter D., c/o Canada Paper Co., Craig Street, Montreal, Canada, Paper Manufacturer.  
 McFarlane, W. W., 613, East 14th Street, Chester, Pa., U.S.A., Dyeworks Manager.  
 McGeorge, A. J. (subs.), 78, Mount Pleasant, Liverpool; and (Journals) 205, West 78th Street, New York City, U.S.A., Analytical Chemist.  
 McGhie, T. Burns, 116, Cumberwell Green, S.E., Analytical Chemist and Assayer.  
 McGill, Dr. J. T., Vanderbilt University, Nashville, Tenn., U.S.A., Adjunct Professor of Chemistry.  
 McGlashan, John, Cawnpore Sugar Works, Cawnpore, India, Technical Chemist.  
 McGowan, John, Ash House, Talke, near Stoke-upon-Trent, Colliery Manager.  
 Machalski, F. J., 159, North Fifth Street, Brooklyn, N.Y., U.S.A., Technical Chemist.  
 McIlhiney, Dr. Parker C., Columbia University, New York City, U.S.A., Chemist.  
 McIlwaine, Alf. W., Stoneferry, Hull, Oil Manufacturer.  
 MacIndoe, G. D., Sunnybank, Paeroa, Ohinemuri, near Auckland, New Zealand, Chemical Works Manager.  
 MacKean, Wm., Incandescent Gas Light Co., Ltd., 14, Palmer Street, Westminster, S.W., Technical Chemist.  
 McKechnie, D., Eccleston Grange, Prescott, Lancashire, Copper Extractor.  
 McKechnie, D. M., Greystone House, Penketh, near Warrington, Copper Extractor.  
 McKellar, W. G., c/o United Alkali Co., Ltd., Eglinton Works, Irvine, N.B., Technical Chemist.  
 McKenna, Dr. Chas. F., 221, Pearl Street, New York City, U.S.A., Chemist.  
 McKenzie, Angus, 52, Water Street, New York, U.S.A., Essential Oils Manufacturer.  
 Mackenzie, Dr. G. S., Sydney Smelting Works, Woolwich, N.S.W., Metallurgical Chemist.  
 Mackenzie, T. E., 3, Stanmore Terrace, Mount Florida, Glasgow, Technical Chemist.  
 Mackenzie, Dr. W. Cossar, Tewfikieh College of Agriculture, Ghizeh, Egypt, Analytical Chemist.

- McKerrow, C. A., 18, Exchange Street, Manchester, Analytical and Consulting Chemist.
- McKesson, John, 91, Fulton Street, New York City, U.S.A., Manufacturing Chemist.
- Mackey, W. McD., Victoria Chambers, Leeds, Analytical Chemist.
- McKillop, Jno., 1, Galveston Road, Putney, S.W., Metallurgist.
- McKinnlay, R. W., Ameliaville, Aytoun Road, Pollokshields, N.B., Metal Merchant.
- Mackinnon, A. K., 12, Popstone Road, South Kensington, S.W.
- MacLean, Alex. S., 31, Bank Street, Greenock, N.B., Soap Refiner.
- McLellan, J. Y., Kaiserstrasse 11, Bernburg, Anhalt, Germany, Chemical Manufacturer.
- McLeod, Professor H., F.R.S., Cooper's Hill, Staines, Professor of Chemistry.
- McLeod, Jas., Westhill, Cardross Road, Dumbarton, N.B., Analytical Chemist and Gas Examiner.
- McMaster, Daniel, McMurray's Royal Paper Works, Wandsworth, S.W., Paper Mill Manager.
- Macmillan, Arch., Chemical Laboratory, 29, Chambers Street, Edinburgh.
- McMillan, W. G., Metallurgical Laboratory, Mason College, Birmingham, Metallurgical Chemist.
- McMullan, Chas., 20, Corn Market, Belfast, Ireland, Soap Works Manager.
- McMurtree, J. M., 21, Princes Street, Pollokshields, Glasgow, Brass Founder.
- McMurtry, G. C., Wallaroo, South Australia, Metallurgist.
- Macnab, C., Lillyburn, Milton of Campsie, N.B., Calico Printer.
- Macnab, W., 14, Great Smith Street, Westminster, S.W., Analytical Chemist.
- Mactear, J., 28, Victoria Street, Westminster, S.W., Chemical Engineer.
- McVie, Jas. P., Tennant's Works, Hebburn-on-Tyne, Analytical Chemist.
- McVitie, Robt., The St. Andrew Biscuit Works, Edinburgh, Biscuit Manufacturer.
- Magnus, Isidor, 52, Leadenhall Street, London, E.C., Chemical Merchant.
- Mahon, R. W., Monongahela Furnaces, McKeesport, Pa., U.S.A., Analytical Chemist.
- Major, J. Lewis, Sealeoates, Hull, Tar Distiller and Chemical Manufacturer.
- Makin, James, Wallhead Mills, Rochdale, Paper Stainer.
- Mallinckrodt, Edw., Mallinckrodt Chemical Works, St. Louis, Missouri, U.S.A., Manufacturing Chemist.
- Mander, S. T., 17, Gracechurch Street, London, E.C.; and (Journals) Varnish Works, Wolverhampton; Varnish Manufacturer.
- Mann, E. A., Fremantle, Western Australia, Government Inspector of Explosives.
- Mann, Harold H., 1, Hebron Road, Hammersmith, W., Chemical Research Student.
- Mann, John C., 19, New City Road, Plaistow, E., Chemist.
- Manning, F. A., 18, Billiter Street, London, E.C., Analytical Chemist.
- Mannington, H. T., Grove House, Halkyn Street, Flint, North Wales.
- Manoukian, Wahan, 173, Palatine Road, Didsbury, Manchester, Analytical Chemist.
- Mansbridge, Wm., 9, The Green, Stratford, E., Chemist.
- Marchlewski, Dr. L., 25, Wellington Street, Higher Broughton, Manchester.
- Markel, Dr. K., Lodge Lane, Warrington, Technical Chemist.
- Markham, A. D., 71, Queen Street, Hull, Pharmaceutical Chemist.
- Marley, J. L., Hebburn-on-Tyne, Iron Founder.
- Marquart, Dr. Paul, Chemische Fabrik Bettenhausen, Bettenhausen - Cassel, Germany, Chemical Manufacturer.
- Marsh, J. T., Ammonia Soda Works, Fleetwood, Lancashire, Chemist.
- Marsh, W., Union Alkali Co., Soho Works, Manchester, Chemical Manufacturer.
- Marshall, Arthur, 65, Fairholme Road, West Kensington, W., Chemist.
- Marshall, Dr. Hugh, Chemistry Department, The University, Edinburgh, Professor of Chemistry.
- Marshall, Francis G., 13, Noble Terrace, Durham Road, Gateshead, Technical Chemist.
- Marshall, Jas., St. Blane's, Paisley, N.B., Chemical Student.
- Marshall, Jas. Burt, Luncearty, Perth, N.B., Bleacher.
- Marshall, Percy S., Bank Top, Lowerhouses, Huddersfield, Assistant Chemist.
- Marshall, Prof. T. Rymer, St. Mung's College, Glasgow, Professor of Chemistry.
- Marshall, Wm., 149, Drake Street, Rochdale, Dyer.
- Marshall, Wm. (Journals), c/o D. G. Rose, Samarang, Java; and (subs.) c/o D. R. Calder Marshall, 49, Queen Street, Edinburgh, Analytical Chemist.
- Martin, Alex. M., Douglas Villa, Dumbeth Road, Coatbridge, N.B., Analytical Chemist.
- Martin, Chas. H., 14, Aldred Street, Creseent, Salford, Oil and Soap Works Assistant Manager.
- Martin, H., Poole, near Wellington, Somerset, Manure Works Manager.
- Martin, N. H., 29, Mosley Street, Newcastle-on-Tyne, Manufacturing Chemist.
- Martin, T. Tremills, Coongan, Marble Bar, Pilbarra, N.W. Australia, Analytical Chemist.
- Martin, W. H., 183b, King's Road, Chelsea, London, S.W., Analytical Chemist.
- Martindale, Wm., 19, Devonshire Street, Portland Place, W., Pharmaceutical Chemist.
- Martineau, Sydney, South Road, Clapham Park, S.W., Sugar Chemist.
- Martino, F. W., 107, Montgomery Road, Sharrow, Sheffield, German Silver Manufacturer.
- Martius, Dr. C. A., 8, Voss Strasse, Berlin, Germany, Colour Manufacturer.
- Martyn, T. Graham, 4, The Avenue, Truro, Cornwall, Metallurgist.
- Martyn, W., Afton House, Hebburn-on-Tyne, Chemical Works Manager.
- Mason, J., Eynsham Hall, Witney, Oxon, Director of Pyrites Co.
- Mason, J. Francis, Eynsham Hall, Witney, Oxon.
- Mason, Thos., Hyson Green Works, Nottingham, Manufacturing Chemist.
- Mason, W. B., 117, Derby Street, Bolton-le-Moors, Pharmaceutical Chemist.
- Masson, Prof. D. Orme, University of Melbourne, Victoria, Australia, Professor of Chemistry.
- Master, Ardesheer B., 679, Tardeo, Bombay, India, Chemical Manufacturer.
- Mather, Colin, Salford Iron Works, Manchester, Engineer.
- Mather, J., Blaydon Chemical Works, Blaydon-on-Tyne, Manager.
- Mather, Wm., Salford Ironworks, Salford, Manchester, Chemical and Mechanical Engineer.
- Matheson, W. J., 178, Front Street, New York, U.S.A., Chemical Merchant.
- Mátos, Louis J., 728, Union Street, Philadelphia, Pa., U.S.A., Chemist.
- Matsui, G., Sakuranomiya, Osaka, Japan; and (Journals) 76, Gower Street, London, W.C., Chemical Engineer.
- Matthews, C. G., St. John's Lodge, Beckenham, Kent, Brewing Chemist.
- Matthews, Donald J., c/o British Aluminium Co., Ltd., Larne Harbour, Ireland, Chemist.
- Mawdsley, W. H., c/o Gold Mining Co., Ltd., Mount Morgan, Queensland, Chemist.
- Maxim, Hudson, 377, Norwood Road, S.E., Explosives Manufacturer.
- Maxwell, Jno., Solway Chemical Works, Silloth, Cumberland, Chemical Manure Manufacturer.
- Maxwell, Thos., 49, Harvie Street, Bridgeton, Glasgow (Journals); and Mossknowe, Braeside Avenue, Rutherglen, Manufacturing Chemist.
- Mayenfeld, Dr. E. von Salis. See under "Salis."

- Mayer, Wm. Turner, c/o Albany Chemical Co., 65-67, Green Street, Albany, N.J., U.S.A., Manufacturing Chemist.
- Mayfield, A. S., c/o S. Tudor and Co., Lead Works, Hull, Analyst.
- Mayfield, H. B., Heanor, near Nottingham, Dyer.
- Mayhew, E. W. A., High Street, Freemantle, Western Australia, Manufacturing Chemist.
- Meacham, Chas. S., Pettridge, Maidstone, Kent, Brewer.
- Mead, Frank, Sutton Gasworks, Surrey, Gas Engineer.
- Meggitt, H. A., Chemical Works, Mansfield, Notts, Manure Manufacturer.
- Meggitt, Loxley, c/o Saml. Meggitt and Sons, Lim., Mansfield, Notts, Analytical Chemist.
- Meikle, Jno., 4, Woodlands Road, Glasgow, Journalist.
- Meisel, C. F. A., 14, Strong Place, Brooklyn, N.Y., U.S.A., Chemist.
- Meldola, Prof. R., F.R.S., 6, Brunswick Square, London, W.C., Professor of Chemistry.
- Meldrum, Jas. Jones, Atlantic Works, City Road, Manchester, Manufacturing Engineer.
- Mellen, Edwin D., c/o Curtis, Davis, & Co., 184, Broadway, Cambridgeport, Mass., U.S.A., Soap Manufacturer.
- Mellon, W. W., 16, Sandymount Road, Dublin, Ireland, Manufacturing Chemist.
- Mellor, S., Magnesium Metal Co., Patricroft, Manchester, Metal Refiner.
- Melville, D. P. O., Box No. 1, Woodmere, Wayne Co., Mich., U.S.A., Chemical Works Manager.
- Mendeleeff, Prof. D., Cadet Line 9, Vassilieff Island, St. Petersburg, Professor of Chemistry.
- Menges, Dr. Franklin, Penna. College, Gettysburg, Pa., U.S.A., Professor of Applied Chemistry.
- Mensching, Dr. C., Crumpsall Vale Works, Blackley, near Manchester, Chemist.
- Menzies, R. C., Inveresk Mills, Musselburgh, N.B., Paper Maker.
- Mercer, C. A., 22, Streathbourne Road, Upper Tooting, S.W., Chemical Apparatus Maker.
- Mercer, J. B., 330, Lower Broughton Road, Manchester.
- Mercer, F. M., 89, Bishopsgate Street, London, E.C., Manufacturing Chemist.
- Mercer, Thos., The Brewery, Edenfield, near Bury, Lancashire, Brewing Chemist.
- Merck, E., Darmstadt, Germany, Manufacturing Chemist.
- Merck, Geo., cor. of University and Clinton Places, New York City, U.S.A., Chemical Manufacturer.
- Merrell, Geo., Lock Box 786, Cincinnati, Ohio, U.S.A., Manufacturing Chemist.
- Messel, Dr. R., 53, Ebury Street, S.W., Chemical Manufacturer.
- Metcalf, Jno., Moorfield, Altham, near Accrington, Tar Distiller.
- Metcalf, Wm., Aspin House, Oswaldtwistle, near Accrington, Tar Distiller.
- Mewburn, J. C., 55 and 56, Chancery Lane, London, W.C., Patent Agent.
- Meyer Max E., 62, Corso Venezia, Milan, Italy, Chemist.
- Michaelis, G., 292, Lark Street, Albany, N.Y., U.S.A., Chemist and Professor of Pharmacy.
- Miles, G. Wellington, jun., 103, Milk Street, Boston, Mass., U.S.A., Analytical Chemist.
- Milestone, W. C., Garrett Lane, Wandsworth, S.W., Chemical Works Manager.
- Miller, Dr. A. K., Kilvert's Buildings, Withy Grove, Manchester, Analytical Chemist.
- Miller, A. Russell, Cambuslang, near Glasgow, Printworks Chemist.
- Miller, E. V., c/o New Zealand Sugar Co., Auckland, New Zealand, Sugar Works Chemist.
- Miller, Geo., Church Cottage, Halewood, Lancashire, Technical Chemist.
- Miller, Dr. Harry E., 1264, 11th Street, Oakland, Cal., U.S.A., Analytical Chemist.
- Miller, Dr. H. von, Beatrixgasse 3211, Vienna, Austria, Chemical Manufacturer.
- Miller, Dr. John A., Niagara University, 203, Ellicott Street, Buffalo, N.Y., U.S.A., Professor of Chemistry.
- Miller, Jno., Messrs. Jas. Black & Co., 11, Exchange Square, Glasgow, Calico Printer.
- Miller, J. Carlile, 89, Rumford Street, Bridgeton, Glasgow, Manufacturing Chemist.
- Miller, J. Hopkins, 23, McAslin Street, Glasgow, Dyeworks Chemist.
- Miller, Jno. Poynter, Sandilands Chemical Works, Aberdeen, Technical Chemist.
- Miller, Dr. N. H. J., Harpenden, near St. Albans, Agricultural Chemist.
- Miller, T. Paterson, The Cairns, Cambuslang, near Glasgow, Dyer and Printer.
- Miller, W. M., Prye Estate, Prov. Wellesley, Penang, S.S., Sugar Chemist.
- Mills, Chas., 21, St. Mary Abbott's Terrace, Kensington, W., Chemist to Colour Works.
- Mills, Prof. E. J., F.R.S., 60, John Street, Glasgow, Professor of Chemistry.
- Milner, E., Hartford Manor, Northwich, Alkali Manufacturer.
- Milnes, Edmund, Seedfield, Bury, Lancashire, Dyeing Extract Maker.
- Miner, Harlan S., c/o Welsbach Light Co., Gloucester City, N.J., U.S.A., Technical Chemist.
- Miniati, T., Penketh, near Warrington, Chemist.
- Misell, D., Commercial Traveller.
- Mistovski, Louis, Broadfield Rubber Works, Heywood, near Manchester, Manager.
- Mitchell, Chas. A., 32, Oakley Crescent, Chelsea, S.W., Analyst.
- Mitchell, J. W., Wood Leigh, Clough Fold, near Manchester, Waste Bleacher.
- Mitchell, Robt., 14, Marchhall Road, Edinburgh, Gas Engineer.
- Mitting, E. K., Dashwood House, New Broad Street, E.C., Chemical Manufacturer.
- Moale, Philip R., c/o Mrs. Polley, 82, Chestnut Street, Asheville, N.C., U.S.A., Analytical Chemist.
- Moffatt-Johnston, J., The Birches, Midcalder, N.B., Chemist.
- Mohr, Dr. B., 69A, Parliament Hill, Hampstead, N.W., Consulting Chemist and Metallurgist.
- Mole, Herbert B., 2, Town St., Shepton Mallet, Somerset, Brewer.
- Molineux, John, C.B., Selsley House, Albert Road, Battersea, S.W., Inland Revenue Inspector.
- Molineux, Roland, 6-8, Jersey Street, Newark, N.J., U.S.A., Colour Work Chemist and Manager.
- Moncrieff, John, Elmside, Balhousie, Perth, N.B., Glass and Ink Manufacturer.
- Mond, Dr. L., F.R.S., 20, Avenue Road, Regent's Park, London, N.W.; and 64, Via Sistina, Rome, Alkali Manufacturer.
- Mond, Robt. L., Winnington Hall, Northwich, Chemist.
- Moodie, W. E., Croftingea Works, Alexandria, N.B., Analytical Chemist.
- Mook, Chas., Donglashall, Westeregeln, Magdeburg, Germany, Alkali Works Director.
- Mooney, M., Chemical Works, 74, Rogerson's Quay, Dublin, Chemical Manufacturer.
- Moore, B. T., Longwood, Bexley, Kent, Civil Engineer.
- Moore, Chas. C., 11, Old Hall Street, Liverpool, Chemist.
- Moore, Dr. Geo. D., 21, Catherine Street, Worcester, Mass., U.S.A., Professor of Chemistry.
- Moore, R. T., 156, St. Vincent Street, Glasgow, Mining Engineer.
- Moore, Thos., Laboratoire du Service Local, Noumea, New Caledonia, Analytical Chemist.
- Moore, Thos., Northwich, Cheshire, Merchant.
- Moore, Wm. F., Lonsdale, Temple Road, Upper Rathmines, Dublin, Wholesale Druggist.
- Moorhouse, J. B., Cecil Mount, Horton Park, Bradford, Dyer.
- Mordle, F. Dare, Fishpond Drive, The Park, Nottingham, Starch Manufacturer.
- Morgan, Albert J., 439, West Street, New York City, U.S.A., Soap Manufacturer.

Morgan, Jno. Jas., 10, Bryntirion Street, Dowlais, Assayer.  
 Morgans, Thos., 60, Queen Square, Bristol, Civil Engineer.  
 Morison, J. Gillies, Southwood, 5, Birdhurst Road, South Croydon, Chemist.  
 Moritz, Dr. E. R., 72, Chancery Lane, London, W.C., Brewing Chemist.  
 Morley, Dr. H. Forster, 47, Broadhurst Gardens, South Hampstead, N.W., Professor of Chemist.  
 Morrell, Jno. B., Holdgate House, York, Cocoa Manufacturer.  
 Morrice, Jas. A., 1, Prince's Terrace, Dowanhill, Glasgow, Starch and Gum Manufacturer.  
 Morris, Dr. G. Harris, 72, Chancery Lane, London, W.C. (Journals), 18, Gwendyr Road, West Kensington, W., Brewing Chemist.  
 Morris, Herbert N., 52, Manley Road, Manchester, Technical Chemist.  
 Morris, J. Haydn, 9, Grosvenor Terrace, Wavertree, Liverpool, Technical Chemist.  
 Morris, R., Doncaster, Chemical Manufacturer.  
 Morrison, Geo. R., Richmond House, Plaistow, Essex, Analytical Chemist.  
 Morrison, J., St. Peter's Chemical Works, Newcastle-on-Tyne, Chemical Engineer.  
 Morson, T., 124, Southampton Row, Russell Square, London, W.C., Manufacturing Chemist.  
 Morton, Jas., Dalquhurn Works, Renton, N.B., Dyeworks Manager.  
 Mosenthal, Henry de, 220, Winchester House, Old Broad Street, London, E.C., Explosives Company Manager.  
 Moss, J., Wilson Street, New Cross Road, London, S.E., Manufacturing Chemist.  
 Moszczenski, J. von, 248, East 52nd Street, New York, U.S.A., Consulting Chemist.  
 Moul, Frank, Aldersgate Chemical Works, Southall, Technical Chemist.  
 Moul, J., Underhill, Low Fell, Gateshead-on-Tyne, Secretary.  
 Moulton, G. L., Soho Mills, Macclesfield, Chemical Manufacturer.  
 Mount, Edw., Oaklands, Aughton, near Ormskirk, Assistant Secretary (United Alkali Company).  
 Muir, J. Martin, c/o Muir Bros. and Co., Moscow, Russia, Chemical Manufacturer.  
 Muir, J. P., 233, Camden Road, London, N.W., Chemist.  
 Muir, Jas. Stanley, c/o G. and S. Extraction Co. of America, Ltd., McPhee Buildings, Denver, Colo., U.S.A., Chemist.  
 Muir, Wm., 5, Angel Place, Upper Edmonton, Middlesex, Merchant.  
 Muir-Smith, W., Carolina Port, Dundee, Manager of Dundee Oil Works.  
 Müller, Geo., P.O. Box 486, Colorado Springs, Col., U.S.A., Chemist.  
 Müller, Dr. H., F.R.S., 13, Park Square East, Regent's Park, London, N.W., Research Chemist.  
 Mundy, Lionel, 27, Merton Road, Kensington, W., Importer of Unfermented Wines.  
 Munro, Dr. J. M. H., Churchfields, Salisbury, Professor of Chemistry.  
 Munroe, Prof. Chas. E., Columbian University, Washington, D.C., U.S.A., Professor of Chemistry and Dean.  
 Murdoch, H. R. M., 4, Nobel's Villas, Stevenston, Ayrshire, Explosives Chemist.  
 Murray, Dr. Thos. S., Chemical Department, The University, Aberdeen, Assistant to Professor of Chemistry.  
 Muspratt, E. K., Seaforth Hall, near Liverpool, Alkali Manufacturer.  
 Muspratt, Max, 2, Mannering Road, Sefton Park, Liverpool, Technical Chemist.  
 Muspratt, S. K., 24, Grove Park, Liverpool, Alkali Manufacturer.  
 Muter, Dr. J., Winchester House, Kennington Road, London, S.E., Chemical Lecturer.  
 Maurling, T. J. R., P.O. Box 2660, New York City, U.S.A., Dyestuff Importer.  
 Myers, Dr. Henry C., Washington State University, Seattle, Wash., U.S.A., Professor of Chemistry.

Myers, Wm. S., 98, Easton Avenue, New Brunswick, N.J., U.S.A., Instructor in Chemistry (New Jersey State Scientific School).

## N

Nadheim, Capt. M., 7, Dumskaya, St. Peter-burg, Russia, Government Engineer.  
 Naef, Dr. P., P.O. Box 473, Kansas City, Mo., U.S.A., Technical Chemist.  
 Napier, J., 89, London Road, Ipswich, Chemist.  
 Napier, Jas., 15, Princes Square, Strathbungo, Glasgow, Manufacturing Chemist.  
 Napier, Jno. W., Gas Works, Auchterarder, N.B., Manager and Chemist.  
 Nason, Carleton W., 74, Beckman Street, New York, U.S.A., Mechanical Engineer.  
 Naylor, Wm., 16, Walton's Parade, Preston, Lancashire, Chief Inspector (Ribble Joint Committee).  
 Naylor, W. A. H., 38, Southwark Street, London, S.E., Manufacturing Chemist.  
 Neill, Geo. D., 26, Forsyth Street, Greenock, N.B., Sugar Refiner.  
 Neilson, James, 107, High John Street, Glasgow, Chemist.  
 Neilson, Thos., c/o Mountain Mining Co., Keswick, Shasta Co., Cal., U.S.A., Metallurgical Chemist.  
 Neilson, Wm., 95, Finlay Drive, Dennistoun, Glasgow, Technical Chemist.  
 Neiman, H. S., 8, East 97th Street, New York City, U.S.A., Colour Chemist.  
 Nelson, Arthur J., c/o Clayton Aniline Co., Ltd., Clayton, Manchester, Chemist.  
 Nesbit, Jas., 19, Wellington Street, Portobello, Edinburgh, Chemical Student.  
 Ness, T., Black Banks Chemical Works, Darlington, Tar Distiller.  
 Newall, F. S., Washington, co. Durham, Chemical Manufacturer.  
 Newall, J. F., 8, Market Place, Manchester, Oil Merchant.  
 Newberry, Spencer B., Sandusky Portland Cement Co., Sandusky, Ohio, U.S.A., Cement Works Manager.  
 Newcomen, Thos., Chemical Works, Lydbrook, near Ross, Wood Distiller.  
 Newlands, B. E. R., 2, St. Dunstan's Hill, London, E.C., Analytical and Consulting Chemist.  
 Newlands, W. P. R., 1, Mildenhall Road, Lower Clapton, N.E., Sugar Chemist.  
 Newsholme, G. T. W., 27, High Street, Sheffield, Pharmaceutical Chemist.  
 Newton, A. H., c/o Winsor and Newton, Ltd., North London Colour Works, Kentish Town, N.W., Artists' Colour Manufacturer.  
 Newton, H. C., Knowle House, Brentwood, Essex, Artists' Colour Manufacturer.  
 Newton, Jno., Park Green, Macclesfield, Silk Dyer.  
 Newton, Jno., Manor Works, Rotherhithe New Road, London, S.E., Manure Manufacturer.  
 Nichols, J. A., Stanley Mount, New Mills, near Stockport, Teacher of Science.  
 Nichols, W. H., 45-47, Cedar Street, New York, U.S.A., Manufacturing Chemist.  
 Nicholson, J. C., Hunslet Chemical Works, Leeds, Chemical Manufacturer.  
 Nickolls, John B., The Laboratory, Grange, Guernsey, Analytical Chemist.  
 Nicol, Dr. W. W. J., 15, Blacket Place, Edinburgh, Chemical Lecturer.  
 Nimmo, J., Penshurst, Stanger Road, South Norwood, S.E., Analytical Chemist.  
 Nishigawa, T., Ryuso Kaisha, Osaka, Japan, Director of Works.  
 Nolting, Dr. E., Ecole de Chimie, Mulhouse, Alsace, Germany, Professor of Chemistry.  
 Norman, F. J., Lyndhurst, Higher Runcorn, Cheshire, Chemical Manufacturer.  
 Norman, J. T., Avalon, Putney Common, S.W., Consulting Chemist.

Norris, Webster, Melrose, Mass., U.S.A., Rubber Works Chemist.  
 Norris, Wm. M., Princeton, N.J., U.S.A., Leather Chemist.  
 North, E. Gordon N., Bella Vista 14, Minas de Rio Tinto, Huelva, Spain, Technical Chemist.  
 Northing, J., The Murrrough, Wicklow, Ireland, Technical Chemist.  
 Norton, Dr. S. A., 363, East Town Street, Columbus, Ohio, U.S.A., Professor of Chemistry (Ohio State University).  
 Norton, Dr. T. H., University of Cincinnati, Ohio, U.S.A., Professor of Chemistry.  
 Nuttall, Harry, c/o Jno. A. Bremner and Co., Albert Street, St. Mary's, Manchester, Oil Manufacturer.

## O

Oakes, Geo. A., Bloomfield, N.J., U.S.A., Woollen Mill Owner.  
 O'Beirne, W. G., British Chemical Works, Clydebank, Glasgow, Manufacturing Chemist.  
 Oddie, Jas., School of Mines, Ballarat, Australia, Chemical Lecturer.  
 Oddy, Robert W., 60, Waterhouse, Toad Lane, Rochdale, Chemist.  
 Odling, Dr. W., F.R.S., 15, Norham Gardens, Oxford and 38, Ladbroke Grove Road, North Kensington, W. Professor of Chemistry.  
 Oehler, K., Offenbach-am-Main, Germany, Colour Manufacturer.  
 Ogata, Saburo, Zohci Shikyoku, Okurasho, Tokyo, Japan, Assayer.  
 Ogilvy, D. J., Gest Street; and C. H. and O. R. R., Cincinnati, Ohio, U.S.A., Manufacturing Chemist.  
 Ogston, G. H., Junior Athenæum Club, Piccadilly, London, W., Analytical Chemist.  
 Ogura, K., Army Survey Department, General Staff, Tokio, Japan, Photographer.  
 Oliver, F., 70, Winchester Street, South Shields, Analytical Chemist.  
 Oliver, Wm. Letts, 1066, 12th Street, Oakland, Cal., U.S.A., Mining Engineer.  
 Ollerenshaw, S., 96, Dayvulme Lane, Urmston, Manchester, Technical Chemist.  
 O'Neill, E. H., Johnson's Saccharum Co., Limited, Stratford, London, E., Managing Director.  
 Orme, J., 65, Barbican, London, E.C., Manufacturing Chemist.  
 Ormerod, John, Croft Head, Littleboro', near Manchester, Tanner and Currier.  
 Orr, A. (subs.), 19, Albion Crescent, Dowanhill, Glasgow; and (Journals) 109, Pitt Street, Sydney, New South Wales, Analytical Chemist.  
 Orr, J. B., Blantyre Lodge, Westcombe Park, London, S.E., Chemical Manufacturer.  
 Orr, Robert, 8, Great Western Terrace, Glasgow, Manufacturing Chemist.  
 Orsman, W. J., Rolurite Explosives Co., Gathurst, near Wigan, Explosives Chemist.  
 Osborne, Thos. B., P.O. Box 485, New Haven, Conn., U.S.A., Chemist.  
 Osmond, Jno. H., c/o Smith, Bell, & Co., Manila, Sugar Works and Technical Chemist.  
 Ostlere, Edward, Messrs. Barry, Ostlere, & Co., Kirkcaldy, N.B., Linoleum Manufacturer.  
 O'Shea, L. T., Firth College, Sheffield, Chemical Lecturer.  
 O'Sullivan, C., F.R.S., 140, High Street, Burton-on-Trent, Brewer and Chemist.  
 O'Sullivan, J., 26, Ashby Road, Burton-on-Trent, Brewing Chemist.  
 Oswell, Benj. L., 71, Spring Terrace Road, Burton-on-Trent, Brewer's Chemist.  
 Oushkoff, P. K., Ekabouga, Govt. of Viatka, Russia, Chemical Manufacturer.  
 Overend, F. L., 59, Rustlings Road, Endcliffe Park, Sheffield, Teacher of Chemistry.

Overtoun, Lord, 7, West George Street, Glasgow, Chemical Manufacturer.  
 Owen, Thos., Henley Grove, Westbury-on-Trym, Bristol.  
 Owens, Caradoc, 88, Great Clowes Street, Lower Broughton, Manchester, Dyer's Manager.  
 Oxland, Robert, 32, Portland Square, Plymouth, Analytical and Consulting Chemist.

## P

Paekard, E., jun., Bramford, near Ipswich, Manure Manufacturer.  
 Page, F. J. M., 54, Sutherland Street, Pimlico, S.W., Chemical Lecturer.  
 Pagés, Albert, 34, Boulevard Henri IV., Paris, Technical Chemist.  
 Paine, Augustus G., 60, Times Building, New York, U.S.A., President of Paper Making Co.  
 Paine, S., c/o F. B. Benger and Co., Ltd., Otter Works, Manchester, Pharmaceutical Chemist.  
 Palmer, T. Chalkley, Box 19, Chester, Pa., U.S.A., Manufacturing Chemist.  
 Palmer, Thos. C., 98, Commercial Road East, London, E., Engineer.  
 Park, J., Millburn Chemical Works, Garngad Hill, Glasgow, Chemical Manager.  
 Parker, Chas. E., Vine House, Penketh, Warrington, Tanner.  
 Parker, Chas. E., c/o Seabury and Johnson, East Orange, N.J., U.S.A., Chemist.  
 Parker, Dr. J. Gordon, Herold's Institute, Drummond Road, Bermondsey, S.E., Head of Tanning School.  
 Parker, Edw., Laburnum House, Rushford Park, Levenshulme, Manchester, Analytical Chemist.  
 Parker, Thos., Manor House, Tattenhall, Wolverhampton, Electrical Engineer.  
 Parker, Thos. J., Bayonne, N.J., U.S.A., Chemical Works Manager.  
 Parry, John, Technical Laboratory, Newport, Mon., Analytical Chemist.  
 Pass, A. C., The Holmes, Stoke Bishop, Bristol, Lead Smelter.  
 Passmore, Dr. F. W., 29, Wolington Road, West Norwood, Analytical and Consulting Chemist.  
 Paterson, Dr. Jas. H. R., 10, Millerfield Place, Edinburgh.  
 Paterson, John, Belle Isle Place, Workington, Cumberland, Mechanical Engineer.  
 Paton, J. M. C., Messrs. Manlove, Alliott, Fryer & Co., Nottingham, Mechanical Engineer.  
 Paton, W. Grant, Greenbank Alkali Works, St. Helens, Lancashire, Alkali Works Manager.  
 Patterson, G., c/o The Manbré Saccharine Co., Ltd., Hammersmith, W., Technical Chemist.  
 Patterson, Harry J., College Park, Prince George's Co., Md., U.S.A., Agricultural Chemist.  
 Patterson, T. L., Messrs. J. Walker & Co., Sugar Refinery, Greenock, N.B., Sugar Works Manager.  
 Pattinson, Dr. H. Salvin, 75 Side, Newcastle-on-Tyne, Analytical Chemist.  
 Pattinson, J., 75, The Side, Newcastle-on-Tyne, Consulting Chemist.  
 Pattison, J., 83, North Oswald Street, Glasgow, N.B., Chemical Merchant.  
 Pattison, Percy J., 95, Ham Park Road, Stratford, E., Colour Chemist.  
 Paul, Dr. Benjamin H., 13, Fenchureh Avenue, E.C.; and (Journals) Parkside, Kingston Vale, Putney, S.W., Consulting and Analytical Chemist.  
 Paul, Jas. H., 123, Palace Road, Tulse Hill, S.W., Analytical Chemist.  
 Pauli, Dr., Höchst a/Main, Germany, Chemical Manufacturer.  
 Payne, J. B., 15, Mosley Street, Newcastle-on-Tyne, Manufacturing Chemist.  
 Peacock, Saml., Finley's Post Office, N.J., U.S.A., Technologist.

- Peak, C. P., Bridgewater Chemical Works, Wigan, Manufacturing Chemist.
- Pearee, Jas. Stanley, Clements, Snarresbrook, Essex, Chemical Manufacturer.
- Pearce, W., Bow Common, London, E.; and (Journals) The Elms, Salway Hill, Woodford, Essex, Chemical Manufacturer.
- Pears, Andrew, jun., Spring Grove, Isleworth, Analytical Chemist.
- Pearson, Frank P., Arnold Printworks, North Adams, Mass., U.S.A., Printworks Manager.
- Pearson, Wm. H., 6, Fenchurch Buildings, London, E.C., Analytical Chemist.
- Pechiney, A. R., Salindres (Gard), France, Alkali Manufacturer.
- Peden, Jno., 30, Ardgowan Street West, Greenock, N.B., Analytical Chemist.
- Pedler, Prof. A., F.R.S., Presidency College, Calcutta, India, Professor of Chemistry.
- Pedler, J. R., 47, Tregunter Road, South Kensington, S.W., Clerk.
- Pemberton, Henry, jun., 1008, Clinton Street, Philadelphia, Pa., U.S., Manufacturing Chemist.
- Péniakoff, D. A., Huy, Belgium, Chemist and Physicist.
- Peniston, Alex. H., Lyndhurst, Theyden Bois, Essex, Pharmaceutical Chemist.
- Penney, Mulgrave D., 11, High Street, Hull, Analytical Chemist.
- Pemington, Alf. J., 8, Church Street, Hanley, Staffordshire, Technical Chemist.
- Pennock, J. D., c/o Solvay Process Co., Syracuse, N.Y., U.S.A., Technical Chemist.

- Phillips, Thos., Birthright View, Cornholme, Todmorden, Wood Distiller.
- Phipson, Dr. T. L., 83, Erpingham Road, Putney Common, S.W., Analytical and Consulting Chemist.
- Picard, Hugh F. K., Deloro P.O., Hastings Co., Ontario, Canada, Metallurgist.
- Pick, Dr. S., Direction der Soda Fabrik, Szezakowa, Galizien, Austria, Chemical Engineer and Manager.
- Pickard, Wm., Stafford Villa, Norfolk Park, Sheffield, Manufacturing Chemist.
- Pickles, H., Prassiate Works, Droylsden, Manchester, Technical Chemist.
- Pielsticker, Carl M., 43, Connaught Road, Harleston, N.W., Chemical Engineer.
- Pilkington, G., Old Market Place, Bury, Lancashire, Analytical Chemist.
- Pilley, Thos. W., 33, Grove Hill Road, Denmark Hill, S.E., Analytical Chemist.
- Pilling, John E., 28, Agnew Villas, Whitegate Lane, Blackpool, Chemist.
- Pipe, Jas., Messrs. Wm. Henderson & Co., Irvine, N.B., Chemical Manufacturer.
- Piper, Walter E., Boston Rubber Shoe Co., Malden, Mass., U.S.A., Chemist.
- Pitblado, L., c/o Mysore G. M. Co., Marikuppam, Mysore, India, Metallurgical Chemist.
- Pitt, T., 16, Coleman Street, London, E.C., Manufacturing Chemist.
- Pittuck, F. W., 19, Stratford Grove, Newcastle-on-Tyne, Technical Chemist.
- Platten, Frank, c/o Elliot's Metal Co., Limited, Selly Oak, near Birmingham, Metallurgical Chemist.
- Platts, Jno. C., 54, Marlborough Road, Moor Oaks, Sheffield, Metallurgical Chemist.
- Plant, Albert, 128, William Street, New York, U.S.A., Wholesale Druggist.
- Playfair, David J., 12, Woodside Terrace, Glasgow, Manufacturing Chemist.
- Pocklington, Hy., 41, Virginia Road, Leeds, Assurance Co.'s Local Manager.
- Pollitt, R. B., c/o New Explosives Co., Ltd., Stowmarket, Suffolk, Civil Engineer.
- Pollock, A., Dillichip Turkey-red Dyeworks, Bonhill, Dumbartonshire, Dyeworks Manager.
- Pomeroy, Dr. Chas. T., 120, Mount Pleasant Avenue, Newark, N.J., U.S.A., Ink Manufacturer.
- Pond, Prof. G. G., State College, Centre Co., Pa., U.S.A., Professor of Chemistry.
- Pond, J. A., 99, Queen Street, Auckland, New Zealand, Analytical Chemist.
- Pont, Pierre S. du, Wilmington, Del., U.S.A., Explosives Manufacturer.
- Poole, Herman, c/o International Phosphate Co., 1, Union Square, New York, U.S.A., Manufacturing Chemist.
- Poole, Thos., 25, Water Street, Liverpool, Chemical Broker.
- Pooley, T. A., 76, Grove Lane, Denmark Hill, S.E., Analytical Chemist.
- Pope, Frank, Estes Park, Colorado, U.S.A., Chemist.
- Pope, S., c/o G. Kynoch and Co., Ltd., Lion Works, Witton, Birmingham, Chemical Works Manager.
- Porter, Herbert, 16, Prince's Road, Crumpsall, Manchester, Alkali Inspector.
- Pott, W. Hamilton, 68, Sumner Street, Southwark Bridge Road, London, S.E., Vinegar Brewer.
- Potter, Chas. E., Love Lane Sugar Refinery, Liverpool, Sugar Works Chemist.
- Potter, Chas. J., Heaton Hall, Newcastle-on-Tyne, Cement Manufacturer.
- Potter, E. P., Fernelough, Bolton-le-Moors, Alkali Manufacturer.
- Potts, Joseph T., Price's Patent Candle Co., Bromboro' Pool, near Birkenhead, Chemist.
- Powell, A. Ernest, Craigowan, Clarendon Road, Whalley Range, Manchester, Oil Merchant.
- Powell, L. S., 5, Campden Hill Square, London, W., Electrician.
- Powter, Philip, Champ D'Or French G. M. Co., Ltd., Johannesburg, S.A.R., Mining Engineer.
- Pratt, Walter E., 1, Lindow Square, Lancaster, Analytical Chemist.
- Prentice, Manning, Stowmarket, Suffolk, Chemical Manufacturer.
- Prescott, Dr. Albert B., Ann Arbor, Mich., U.S.A.
- Preston, Alf., 4, Market Street, Bury Lancashire, Chemist.

- Preston, E. S., Park House Cottage, Park Road, Swanage, Civil Engineer.
- Preston, R., Mill Fud, Holcombe, near Manchester, Manufacturing Chemist.
- Price, A. F., 524, Sacramento Street, San Francisco, Cal., U.S.A., Analytical Chemist.
- Price, Raymond B., c/o Boston Woven Hose and Rubber Co., Cambridgeport, Mass., U.S.A., Chemical Engineer.
- Price, T. Spiers, 15, Seething Lane, London, E.C., Secretary.
- Prinz, Dr. Otto, Sesto Fiorentino, Italy, Editor.
- Pritchard, Edgar J., Burrows, Swansea, Works Manager.
- Pritchard, W. S., Farnworth, Widnes, Chemical Works Manager.
- Prochazka, Dr. Geo. A., 138, West 13th Street, New York, U.S.A., Colour Manufacturer.
- Procter, C., Government Laboratory, Somerset House, London, W.C., and (Journals) 359, Upland Road, Dulwich, S.E., Analytical Chemist.
- Procter, H. B., Yorkshire College, Leeds; and (Journals) Thornleigh, Wheatley Road, Ilkley, Yorks, Lecturer on Tanning.
- Procter, J. W., Skeldergate Bridge, York, Manure Manufacturer.
- Procter, Miss Anne J., Free Library, Widnes, Librarian.
- Procter, W. W., 33, The Side, Newcastle-on-Tyne, Assayer and Analytical Chemist.
- Proude, Jas., 30, Cromwell Terrace, Halifax, Yorks, Soap Works Chemist and Manager.
- Pullar, Herbert S., Rosebank, Perth, N.B., Dyer.
- Pullar, Sir Robert, Pullar's Dyeworks, Perth, N.B., Dyer.
- Pullar, R. D., Pullar's Dyeworks, Perth, N.B., Dyer.
- Pureell, M. F., 13, Victoria Street, Westminster, S.W., Consulting Chemical Engineer.
- Purdie, Dr. Thos., F.R.S., 14, South Street, St. Andrews, N.B., Professor of Chemistry.
- Pütz, Mrs. Helen, 16-17, Great St. Helens, London, E.C., Chemical Merchant.

## Q

- Queeny, John F., c/o Merck and Co., New York, U.S.A., Chemical Merchant.
- Quibell, Oliver, Magnus Lodge, Newark-on-Trent, Manure Manufacturer.
- Quinke, Dr. F., Chemische Fabrik Rhenania, Stolbergh bei Aachen, Germany, Analytical Chemist.
- Quinn, J., Cardwell, Rubber Tyre Manufacturing Co., Ltd., Aston Cross, Birmingham, Chemist and Manager.

## R

- Rademacher, H. A., 7, Lee Street, Lawrence, Mass., U.S.A., Consulting Technical Chemist.
- Rae, G., c/o Mrs. Dalrymple, 599, Great Eastern Road, Glasgow, Assayer.
- Raegener, Louis C., 280, Broadway, New York, U.S.A., Lawyer.
- Ramsay, Dr. W., F.R.S., University College, Gower Street, London, W.C.; Journals to 12, Arundel Gardens, W., Professor of Chemistry.
- Ramsay, W., 15, Lime Grove, Seaforth, Liverpool, Chemist and Assayer.
- Ramsden, Edw., 11, Cecil Avenue, Horton Park, Bradford, Spinner.
- Ramsden, J., Lion Brewery, Belvedere Road, Lambeth, London, S.E., Brewer.
- Raper, Arthur E., Alston House, Thornton Road, Bradford, Yorks, Works Chemist.
- Raphael, Ralph, 59, Moorgate Street, London, E.C., Solicitor.
- Rapkin, J. B., c/o Waterlow and Sons, Ltd., Skinner Street, Finsbury, E.C., Stationer.
- Ratcliff, F. D., 71, Pershore Road, Birmingham, Vinegar Brewer.
- Rau, Dr. H. M., 130-132, Pearl Street, New York, U.S.A., Chemist.
- Rawcliffe, H., Gillibrand Hall, Chorley, Lancashire, Analytical Chemist.
- Rawlins, T. Beilby, Glasgow, Colour Works Chemist.
- Rawson, C., 2, Melbourne Place, Bradford, Analytical and Consulting Chemist.
- Rawson, Dr. S. G., Technical Schools, Huddersfield, Analytical Chemist.
- Raymond, C. W., 65, Clova Road, Forest Gate, E., Chemical Works Inspector.
- Rayner, J. A. E. (Journals), Kirkstone Brow, Ambleside, and Grove House, Wavertree, Liverpool, Alkali Manufacturer.
- Read, E. J., 2, Leigh Terrace, Amptill Road, Bedford, Analyst.
- Reade, Thos., Oakleigh, Compton, near Wolverhampton, Manufacturing Chemist.
- Readman, Dr. J. B., Chemical Laboratory, 4, Lindsay Place, George IV. Bridge, Edinburgh, Analytical and Consulting Chemist.
- Reddrop, J., Laboratory, L. & N. W. Railway, Crewe, Analytical Chemist.
- Redfern, G. F., 4, South Street, Finsbury, London, E.C., Patent Agent.
- Redgate, J. G., Traffic Street, Nottingham, Aërated Water Manufacturer.
- Redwood, B., 4, Bishopsgate Street Within, London, E.C., Petroleum Expert.
- Redwood, I. I., Technical Chemist.
- Redwood, Robt., 4, Bishopsgate Street Within, London, E.C., Secretary.
- Redwood, T. Horne, 15, Red Lion Square, W.C., Analytical Chemist.
- Rée, Dr. A., Guildhall Chambers, Lloyd Street, Manchester, Aniline Dye Manufacturer.
- Reed, Albert E., Beigrave House, Maidstone, Kent, Paper Works Chemist.
- Reed, Dr. J. Hastings, c/o Colonial Sugar Refining Co., Ltd., O'Connell Street, Sydney, N.S.W., Sugar Manufacturer.
- Reekie, J. A., 5, Simmondley Lane, Glossop, Derbyshire, Calico Printer's Colour Mixer.
- Reeks, T. H., 39, Tierney Road, Streatham Hill, S.W., Analytical Chemist.
- Reibstein, Dr. Tuisko, Radebeul, bei Dresden, Germany, Maltose Chemist.
- Reid, Robt., Oil Mills, Horbury Bridge, near Wakefield, Chemical Student.
- Reid, T. Anderson, Lostock Gralam, Northwich, Works Manager.
- Reid, Walter C., 20, Percy Park Road, Tynemouth, Manufacturer.
- Reid, Wm., jun., Bombay Dyeworks, Dadur, Bombay, India, Dyer.
- Reid, W. F., Fieldside, Addlestone, Surrey, Technical Chemist.
- Reid, W. G., Soap Works, Beaconsfield, South Africa, Technical Chemist.
- Remfry, H. H., 3, Fancy Laue, Calcutta, India, Patent Agent.
- Renaut, F. W., The Brambles, Elmbourne Road, Tooting Common, S.W., Secretary.
- Rennie, Dr. E. H., University of Adelaide, South Australia, Professor of Chemistry.
- Renoldson, W. L., c/o United Alkali Co., Lim., Allhusen's Works, Gateshead, Chemical Works Manager.
- Reoch, R., River Point, Rhode Island, U.S.A., Print Works Manager.
- Rettie, Theodore, P.O., Johannesburg, S.A.R.; and (Journals) 16, Great King Street, Edinburgh, Metallurgical Chemist.
- Reubens, Chas. M., 77, East 115th Street, New York, U.S.A., Chemist.
- Renter, Dr. L., c/o Merck and Co., University and Clinton Places, New York, U.S.A., Chemist.
- Reynolds, Henry C., Thornclyff, Lausdown Road, Cheltenham.
- Reynolds, Dr. J. Emerson, F.R.S., Trinity College, Dublin, Professor of Chemistry.
- Reynolds, R., 13, Briggate, Leeds, Pharmaceutical Chemist.
- Rhodes, E., c/o Thos. Vickers & Sons, Widnes, Technical Chemist.

- Rhodes, Jos., Beech House, Newtown, via Stockport, Print Works Chemist.
- Ricarde-Seaver, Major F. J., 16, Grafton Street, Bond Street, W., Metallurgist.
- Richards, Edgar, 311, West 88th Street, New York, U.S.A., Analytical Chemist.

- Richardson, Clifford, Laboratory, Barber Asphalt Paving Co., Long Island City, N.Y., U.S.A., Chemical Engineer and Consulting Chemist.
- Richardson, C. T., Monkton Lodge, Jarrow-on-Tyne, Alkali Manufacturer.
- Richardson, D. B., 23, Tierney Road, Streatham Hill, S.W., Chemical Merchant.
- Richardson, F. W., 2, Farellife Place, Bradford, Yorkshire, Analytical Chemist.
- Richardson, G. E., Branch House, Batley, Yorks, Manufacturing Chemist.
- Richardson, Jas. C., 19, Claremont Square, London, N., Electrochemical Engineer.
- Richardson, S. M., 115, Main Street, Bonhill, N.B., Analytical Chemist.
- Richardson, Walter W., 1, Montpelier Terrace, Cliff Road, Leeds, Manufacturing Chemist.
- Richardson, Wm. H., Newsky Thread Mills, Malaja Bolotnaja, St. Petersburg, Russia, Textile Chemist.
- Richmond, H. D., Rodbourne, Claremont Road, St. Margaret's, Twickenham, Chief Chemist (Aylesbury Dairy Co.).
- Richmond, W. H., Liver Alkali Co., Limited, Ditton Road, Widnes, Alkali Manufacturer.
- Riddell, R., 87, Horninglow Street, Barton-on-Trent, Brewer.
- Ridding, Howard C., A.R.S.M., 20, Algernon Road, Birmingham, Analytical Chemist.
- Riden, Dr. Samuel, Chemical Laboratory, 28, Victoria Street, Westminster, S.W., Analytical and Consulting Chemist.
- Ridsdale, C. H., Hutton Grange, Guisboro', Yorks, Analytical Chemist.
- Rigby, John S., 35, Bagot Street, Wavertree, Liverpool, Chemical Manufacturer.
- Riker, Jno. J., 45, Cedar Street, New York City, U.S.A., Merchant.
- Riley, E., 2, City Road, Finsbury Square, London, E.C., Metallurgical Chemist.
- Riley, Jas., 168, St. Vincent Street, Glasgow, Steel Manufacturer.
- Riley, J. E., Arden Hall, near Accrington, Chemical Manufacturer.
- Riley, J., Hapton Chemical Works, Accrington, Chemical Manufacturer.
- Riley, James, Chemical Works, Oakenshaw, near Accrington, Lancashire, Technical Chemist.
- Riley, Jno., Thornliebank, near Glasgow, Print Works Manager.
- Riley, Wm., Castleton, Manchester, Chemical Manufacturer.
- Rintoul, Wm., Royal Gunpowder Factory, Waltham Abbey, Essex, Explosives Chemist.
- Ripley, H., Bowling Dyeworks, Bradford, Yorkshire, Dyer.
- Ritchie, Robt., Shawfield Works, Rutherglen, near Glasgow, Technical Chemist.
- Ritson, T. N., Gas Works, Kendal, Gas Engineer.
- Rix, W. P., Khöswen, Gap Road, Wimbledon, Potter.
- Robbins, J., 147, Oxford Street, London, W., Pharmaceutical Chemist.
- Roberts, C. F., Linfitts, Delph, via Oldham, Chemical Merchant.
- Roberts, Ernest H., Hollydale, Allfarthing Lane, Wandsworth, S.W., Analytical Chemist.
- Roberts, F. A., Cornbrook Chemical Works, Manchester, Chemical Manufacturer.
- Roberts, F. G., Adair, Lion House, Amburst Park, Stamford Hill, N., Chemical Manufacturer.
- Roberts, J. H. M., 14, St. James' Road, Brixton, S.W., Brewer.
- Roberts, R. Wightwick, 22, Calle Arturo Prat, Valparaiso, Chili, Analytical and Consulting Chemist.
- Robertshaw, C. Dawson, c/o Dr. Lewkowsch, Lancaster Avenue, Fennell Street, Manchester, Chemist.
- Robertson, Alex., Argyle Chemical Works, Oban, N.B., Manufacturing Chemist.
- Robertson, Alex. A., Australian Alum Works, Runcorn, Cheshire, Technical Chemist.
- Robertson, Geo. H., 30, Hem-stall Road, West Hampstead, N.W., Electro Chemist.
- Robertson, Robt., Royal Gunpowder Factory, Waltham Abbey, E., Analytical Chemist.
- Robertson, R. A., 8, Park Street East, Glasgow, Mechanical Engineer.
- Robins, Walter, 9, Northbrook Road, Lee, S.E., Chemist.
- Robinson, D., Montrose and Seneca Avenues, Brooklyn, N.Y., U.S.A., Manufacturing Chemist.
- Robinson, G. C., Royal Institution, Hull; and Laboratory, Bond Street, Hull (for Journals), Chemical Lecturer.
- Robinson, H. H., Imperial College, Hankow, China, Professor of Chemistry.
- Robinson, Jos., Farnworth, Widnes, Chemical Manufacturer.
- Robinson, Jno., c/o C. and L. Shaw, Huyton Quarry, near Liverpool, Chemical Engineer.
- Robinson, Thomas, 401, West Street, Glasgow, Chemical Works Manager.
- Robson, Jas., 204, George Street, Glasgow, Chemist.
- Rodda, Edw. D., 6, Gold Street, Routh, Cardiff, Engineer.
- Rodger, Edw., 1, Clairmont Gardens, Glasgow, W.
- Rogers, Harry, 5, Stoke Newington Common, London, N., Secretary (Victoria Stone Co.).
- Rogers, Capt. Jno. Martin, Mount Hawke, Scorrier, Cornwall, Mining Engineer.
- Rogerson, W. J., 38, Southwark Street, London, S.E., Wholesale Druggist.
- Rollin, J. C., 1, St. Nicholas Buildings, Newcastle-on-Tyne, Secretary.
- Roscoe, Sir Henry, F.R.S., 10, Bramham Gardens, South Kensington, S.W., Consulting Chemist.
- Roscow, Jno. F., Merrimac Printworks, Lowell, Mass., U.S.A., Print Works Chemist.
- Rosell, Dr. Claude A. O., 100, East 17th Street, New York, U.S.A., Chemist.
- Roseuheim, Dr. Otto, 68, Belsize Park Gardens, Hampstead, N.W., Analytical and Research Chemist.
- Ross, Alex. J. J., Tayavalla, Falkirk, N.B., Chemical Manufacturer.
- Ross, Arthur, 1, Glengall Road, Old Kent Road, London, S.E., Analytical Chemist.
- Ross, J. G., 28, Gainsboro' Road, Wavertree, Liverpool, Analytical Chemist.
- Rothwell, C. F. Seymour, 88, George Street, Moss Side, Manchester, Print Works Chemist.
- Rothwell Rich. P., Room 366, 20, Bucklers-bury, E.C., Editor "Engineering and Mining Journal."

 Salis-Mayenfeld, Dr. E. von., c/o Hohenhausen & Co., Ltd., Blackley, near Manchester, Technical Chemist.  
 Salmon, E. H. R., 70, Kenninghall Road, Lower Clapton, N.E., Analytical Chemist.  
 Salt, Arthur P., Sunnyside, Pinner Road, Harrow, Analytical Chemist.  
 Salter, Chas. T. C., 33, Park Hall Road, East Finchley, N., Scientific Journalist.  
 Saltmarsh, J. G., West Mount, Upton, Macclesfield, Works Chemist.  
 Samuel, W., Cobden, 337, Norwood Road, West Norwood, S.E., Analytical Chemist.  
 Samuelson, Rt. Hon. Sir Bernard, Bart., F.R.S., 56 Prince's Gate, London, S.W., Ironmaster.  
 Samuelson, Francis A. E., Sir B. Samuelson and Co., Ltd., Middlesbrough, Ironmaster.  
 Samuelson, Godfrey B., c/o Messrs. W. T. Glover & Co., Salford, Electrical Manufacturer.  
 Sanlerson, John, P.O. Box 84, Middlesbrough, Kentucky, U.S.A., Chemist.  
 Sandon, R., 42, Lewisham Road, Dartmouth Park, N.W., Examiner at Patent Office.  
 Sandys, Hon. Michael, Pyrford Place, Ripley, Surrey, Stockbroker.  
 Sanford, P. Gerald, Analytical Laboratory, 20, Cullum Street E.C., Analytical and Consulting Chemist.  
 Saniter, E. H., 16, Swinley Road, Wigan, Analytical Chemist.  
 Sankey, Chas. H., Iron Bridge and Essex Wharves, Canning Town, E., Fire- and Acid-Proof Goods Maker.  
 Sauer, Dr. Ewald, c/o Max Kachler and Martini, Wilhelmstrasse 50, Berlin, W., Chemist.  
 Saunders, Walter M., Olneyville, R.I., U.S.A., Analytical Chemist.  
 Savage, Arthur E., Sulphide Corporation Works, Coedles Creek, Newcastle, New South Wales, Metallurgist.  
 Savage, W. W., 109, St. James's Street, Brighton, Pharmaceutical Chemist.  
 Sawers, Wm. D., Balaghat Mysore Mines, Oorgaum, Mysore State, South India, Chemist.  
 Sawyer, Harris E., 37, Gates Street, South Boston, Mass., U.S.A., Chemist.  
 Sayer, Harry, Hawk Street, Carnforth, Lancashire, Analytical Chemist.  
 Sayers, Jos. J., Mayville, Stevenston, Ayrshire, Explosives Chemist.  
 Scales, F. Shillington, Wearmouth Paper Mill, Sunderland, Paper Maker.  
 Sehaek-Sommer, Dr. G., 12, Upper Woburn Place, London, W.C., Sugar Refiner.  
 Schad, Julius, York Buildings, 33, Mosley Street, Manchester, Aniline Co.'s Agent.  
 Schad, Dr. Philip, Winnington Park, Northwich, Technical Chemist.  
 Schläppi, Dr. H., Miltödi, Canton Glarus, Switzerland, Analytical Chemist.  
 Scheel, Wm. H., 78, Pine Street, New York City, U.S.A., Manufacturing Chemist.  
 Schellhaas, H., Thornhill, Beach Road, Hartford, Northwich, Mechanical Engineer.  
 Scheurer-Kestner, Dr. A., 8, Rue Pierre-Charron, Paris, France, Chemical Manufacturer.  
 Schidrowitz, Dr. P., 102, Oxford Gardens, Notting Hill, W., Research Chemist.  
 Schieffelin, Dr. W. Jay, 841, Southern Boulevard, New York, U.S.A., Manufacturing Chemist.  
 Schiller, Louis J., The American Sugar Refining Co., Granite Street, South Boston, Mass., U.S.A., Chemist.  
 Schleicher, Francis J., 38, West Tenth Street, Long Island City, N.Y., U.S.A., Printing Ink and Varnish Chemist.  
 Schlesinger, Dr. Jas., P.O. Box 368 Pretoria, S.A.R., Analytical Chemist.  
 Schlichter, Dr. H., Thothmes House, Gisburn Road, Hornsey, N., Textile Chemist.  
 Scholefield, H. E., Greenwood, Victoria Park, Wavertree, Liverpool, Chemical Manufacturer.  
 Schriever, John, Greenpoint Chemical Works, Brooklyn, N.Y., U.S.A., Manufacturing Chemist.  
 Schroeder, E. August, c/o Church and Co., 36, Ash Street, Brooklyn, N.Y., U.S.A., Chemist.  
 Schryver, Dr. S. B., University College, Liverpool, Assistant Lecturer on Chemistry.  
 Schulze, Dr. Karl E., Chemische Fabrik Lindenhof, Waldhof bei Mannheim, Germany, Technical Chemist.  
 Schunck, Dr. E., F.R.S., Kersal, near Manchester, Colour Chemist.  
 Schüpphaus, Dr. Robt. C., 118, Pennsylvania Avenue, Brooklyn, N.Y., U.S.A., Consulting Chemist.  
 Schwab, Dr. L. C., Sedanstrasse 53, Bernburg, Anhalt, Technical Chemist.  
 Schweich, Emil, 110, Fenchurch Street, London, E.C., Technical Chemist.  
 Schweitzer, Dr. H., 77, William Street, New York City; and (Journals) 149, Dwight Place, Englewood, N.J., U.S.A., Analytical Chemist.  
 Scott, Andrew, 2, Teviot Terrace, Kelvin-side, Glasgow, Analytical Chemist.  
 Scott, Andrew R., Carntyne Chemical Works, Parkhead, Glasgow, Manufacturing Chemist.  
 Scott, Ernest G., 67, Lord Street, Liverpool, Soap Works Chemist.  
 Scott, Herbert, c/o Gerspacher and Co., Usina Wigg Miguel Burnier, Minas, Brazil, Metallurgist.  
 Scott, Jno. Gillespie, Annislea, Northfield, Liberton, near Edinburgh, Analytical Chemist.  
 Scott-Smith, G. E., 67, Surrey Street, Sheffield, Analytical Chemist.  
 Scott, Wm., 168, Eglinton Road, Plumstead, S.E., Sugar Chemist.  
 Scovell, M. A., Lexington, Kentucky, U.S.A., Agricultural Chemist.  
 Scrutton, Willis, Cne, West Australia, Analytical Chemist.  
 Serymgeour, A., c/o African Gold Recovery Co., Box 1283, Johannesburg, S.A.R., Assayer.  
 Serymgeour, Wm., Chemist.  
 Seudder, F., Mersey and Irwell Joint Committee, 44, Mosley Street, Manchester, Analytical Chemist.  
 Seabrooke, H. Cecil, Laboratory, The Brewery, Reading, Research Chemist.

- Searl, Albert, Montreux, Victoria Road, Sideup, Kent, Manager (Bovril, Ltd.).
- Sedding, G. H. P., Auita, Citrus Co., Florida, U.S.A., Chemist.
- Sefton-Jones, Herbert, c/o W. P. Thompson and Co., 322, High Holborn, W.C., Analytical Chemist.
- Segner, P., 26, Princess Street, Manchester, Chemical Agent.
- Seldner, Rudolph, 217, Jefferson Avenue, Brooklyn, New York, U.S.A., Instructor in Chemistry.
- Semet, Louis, 247, Chaussée de Vleurgat, Brussels, Alkali Manufacturer.
- Senger, Roht., 174, Pearl Street, New York City, U.S.A., Manufacturing Chemist.
- Settle, Wm., Brunswick House, Haulgh, Bolton, Mining Engineer.
- Sevin, C., c/o Dollman & Pritchard, 39, King Street, Cheap-side, E.C., Chemical Engineer and Oil Refiner.
- Sewell, Parker, 241, South Frederick Street, South Shields, Analytical Chemist.
- Sexton, Prof. A. Humboldt, 204, George Street, Glasgow, Professor of Chemistry.
- Seyler, Clarence A., Technical Institute, Nelson Terrace, Swansea, Chemist and Assayer.
- Seymour, J. R. W., Northeroft Farm, Inkpen, near Hungerford, Berks.
- Seymour-Jones, A., Cambrian Leather Works, Wrexham, Leather Manufacturer.
- Shadwell, J. E. L., Meadowbank, Melksham, Wilts, Analytical Chemist.
- Shallcross, Arthur, Excelsior Chemical Works, Corbett Street, Bradford, near Manchester, Chemical Manufacturer.
- Shallcross, T. H., Corbett Street, Bradford, near Manchester, Manufacturing Chemist.
- Shanks, Arch., Bridgend Mills, Dalry, Ayrshire, N.B., Chemist.
- Shapleigh, W., Welsbach Incandescent Gas Light Co., Gloucester City, N.J., U.S.A., Technical Chemist.
- Shapley, Fred., 2637, Webster Avenue, Fordham, New York City, U.S.A., Paint and Colour Chemist.
- Sharp, Henry, 11, Delahay Street, Westminster, S.W., Civil Engineer.
- Sharp, James, The Towers, Low Moor, near Bradford, Yorks, Dyer.
- Sharpe, Granville H., 11 & 12, Great Tower Street, London, E.C., Analytical Chemist.
- Sharples, Stephen P., 13, Broad Street, Boston, Mass., U.S.A., Analytical Chemist.
- Sharpley, Wm. P., Ditton Copper Works, Widues, Lancashire, Analytical Chemist.
- Shaw, F. W., 99, Heapey Road, Chorley, Lancashire, Bleach Works Chemist.
- Shaw, Geo., 35, Temple Row, Birmingham, Patent Agent.
- Shaw, Saville, Durham College of Science, Newcastle-on-Tyne, Chemical Demonstrator.
- Shearer, A., 36, Demesne Road, Alexandra Park, Manchester, Technical Chemist.
- Sheffield, Oscar E., Ferntower Road, Canonbury, N., Chemical Student.
- Sheman, G. W., c/o Boston Woven Hose and Rubber Co., Cambridgeport, Mass., U.S.A., Chemical Engineer.
- Shenstone, W. A., Clifton College, Bristol, Chemical Lecturer.
- Shenton, Jas. P., 34, Lansdowne Road, Albert Park, Didsbury, Manchester, Analytical Chemist.
- Shepard, Dr. Chas. U., 68, Meeting Street, Charleston, S.C., U.S.A.
- Shepherd, H. H. B., Anglo-Continental Guano Works, Tidal Basin, Victoria Docks, E., Chemist.
- Shepherd, Jas., Rossend Castle, Burntisland, N.B., Floor-cloth Manufacturer.
- Sheppee, Lt.-Col. F. F., Birtley House, Chester-le-Street, Co. Durham, Colliery Proprietor.
- Sherman, G. W., c/o Boston Woven Hose and Rubber Co., Cambridgeport, Mass., U.S.A., Chemical Engineer.
- Shidzuki, Iwaichiro, c/o Nippon Chemical Manufacturing Co., Onoda, Yamaguchi-ken, Japan, Chemist.
- Shield, H., c/o Messrs. Fawcett, Preston, & Co., Ltd., 17, York Street, Liverpool, Civil Engineer.
- Shields, Dr. J., University College, London, W.C., Chemist.
- Shimomura, K., c/o Sekizen Ginko, 61, Inabashi Shichome, Osaka, Japan, Professor of Chemistry.
- Shimose, Masachika, Kaigun Zobeisho, Tokyo, Japan, Chemical Engineer.
- Shishkoff, Sergius A., Wood Distillery, Korsun, Govt. of Simbirsk, Russia, Manager.
- Shishkoff, Waldemar A., Korsun, Simbirsk, Russia, Chemical Engineer.
- Shutt, Frank T., Central Experimental Farm, Ottawa, Canada, Agricultural Chemist.
- Siebold, L., Broomville Avenue, Sale, Manchester, Analytical Chemist.
- Sill, T. T., c/o United Alkali Co., Ltd., Weston Works, near Runcorn, Alkali Works Manager.
- Sillar, W. Cameron, The Native Guano Co., Limited, 29, New Bridge Street, Blackfriars, E.C., Director (Native Guano Co.).
- Silvester, Harry, Holyhead Road, Handsworth, Birmingham, Analytical and Consulting Chemist.
- Simomura, T. K., c/o C. and J. Favre-Brant, Kawaguchi, Osaka, Japan, Technical Chemist.
- Simon, H., 20, Mount Street, Manchester, Civil Engineer.
- Simonds, Dr. F. M., 20, Platt Street, New York, U.S.A., Mining Engineer and Assayer.
- Simpson, Chas. H., Moor Top House, Ackworth, Pontefract, Soap Manufacturer.
- Simpson, W. S., 95, Darent Road, Stamford Hill, N., Analytical Chemist.
- Sims, T. H., Mayfield Printworks, Manchester, Printworks Chemist.
- Sinclair, Dr. Wm., Young's Oil Co., Lim., Uphall, N.B., Chemist.
- Sindall, R. W., 123, Park Road, Sittingbourne, Kent, Paper Mills Chemist.
- Singer, Ignatius, The Poplars, Capel Street, Calverley, Yorks, Manufacturing Chemist.
- Sisson, G., jun., c/o Washington Chemical Co., Lim., Washington Station, R.S.O., Co. Durham, Works Manager.
- Skaife, Wilfred T., 630, Sherbrooke Street, Montreal, Canada, Sugar Chemist.
- Skelton, John R., Thorpe St. Andrew, Norwich, Technical Chemist.
- Skilton, C. F. E., c/o Messrs. Ind, Coope, & Co., Burton-on-Trent, Brewer.
- Skrurray, Thos., United Breweries, Abingdon, Berks, Brewer.
- Slade, H. E., Streatham Common, London, S.W., Rubber Works Manager.
- Slater, H. H., Laboratory and Testing Office, Grays, Essex, Portland Cement Expert.
- Slater, Sydney H.,
- Slatter, Geo. W., Saltaire Works, Shipley, Yorkshire, Analytical Chemist.
- Slocum, Frank L., Linden Avenue, E.E., Pittsburgh, Pa., U.S.A., Chemist.
- Smail, J. I., Blackmount, Chislehurst, Kent, Chemical Manufacturer.
- Smetham, A., 18, Brunswick Street, Liverpool, Analytical Chemist.
- Smiles, Jas., Blandfield Chemical Works, Canonmills, Edinburgh, Manufacturing Chemist.
- Smith, Alfred, Excelsior Chemical Works, Clayton, Manchester, Manufacturing Chemist.
- Smith, Andrew T., jun., 24, King Street, Liverpool, Chemical Broker.
- Smith, Bernard E., 45, Percy Park, Tynemouth, Alkali Works Inspector.
- Smith, E. Ellsworth, 262, Fifth Avenue, New York, U.S.A., Consulting Physiological Chemist.
- Smith, Edgar B., Prince Regent's Wharf, Silvertown, E., Chemist.
- Smith, Edgar F., 35, Amptill Square, Hampstead Road, London, N.W., Analytical Chemist.
- Smith, Ernest A., Metallurgical Laboratory, Royal College of Science, South Kensington, S.W., Assistant Instructor in Assaying.
- Smith, Francis P., 152, West 77th Street, New York, U.S.A., Chemist.

- Smith, Fred., Box 1324, Johannesburg, S.A.R., Analytical Chemist.
- Smith, G., Polmont Station, Scotland, Explosives Works Manager.
- Smith, G. Henderson, Clerniston, Green Bank Road, Sefton Park, Liverpool, Chemist.
- Smith, Geo. J., Messrs. Bickford, Smith, & Co., Ltd., Tuckingmill, Cornwall, Fuse Manufacturer.
- Smith, Harold Wilson, c/o Tabor, Trego, & Co., Varnish Works, Bow Common, E., Chemical Engineer.
- Smith, Harry, 3, St. Thomas' Terrace, Newcastle-on-Tyne, Technical Chemist.
- Smith, Harry E., 133, 26th Street, Milwaukee, Wis., U.S.A., Analytical Chemist.
- Smith, H. R., 1, Aubert Park, Highbury, London, N., Analytical Chemist.
- Smith, H. Wood, c/o May and Baker, Lim., Battersea, S.W., Analytical Chemist.
- Smith, Jas. F., 139, Stratford Road, Sparkhill, Birmingham, Analytical Chemist.
- Smith, J., Ash Grove House, Radcliffe, Manchester.
- Smith, Dr. J. H., Wollishofen, Zurich, Switzerland, Chemical Lecturer.
- Smith, J. Johnstone, Lockwood Brewery, Huddersfield, Brewing Chemist.
- Smith, Joseph Kent, The Cottage, Glascoed, near Wrexham, Metallurgical Chemist.
- Smith, J. Tertius, c/o Jeyes' Sanitary Compound Co., Ltd., Plaistow, Essex, Technical Chemist.
- Smith, Jno. W., 7, Brookfield Street, Roslindale, Boston, Mass., U.S.A., Analytical Chemist.
- Smith, J. Wm., Solvay Process Co., Syracuse, N.Y., U.S.A., Alkali Works Manager.
- Smith, Linton, Messrs. Smith and Painter, Wilmington, Del., U.S.A., Manufacturing Chemist.
- Smith, R. Greig, Durham College of Science, Newcastle-on-Tyne, Analytical Chemist.
- Smith, R. Watson, Young's Oil Co., Ltd., Chemical Works, Bathgate, N.B., Chemical Works Manager.
- Smith, S., 35, Amphill Square, Hampstead Road, London, N.W., Analytical Chemist.
- Smith, T. Reader, Urban District Council, Kettering, Surveyor, Assoc. M. Inst. C.E.
- Smith, Walter E., 17, Jenkins Street, Providence, R.I., U.S.A., Instructor in Chemistry.
- Smith, Watson, 34, Upper Park Road, Haverstock Hill, N.W., Editor of Society's Journal.
- Smith, Wilfred, 182, West Street, Glasgow, Chemical Manufacturer.
- Smith, W., 10, Corn Street, Bristol, Chemical Merchant.
- Smith, W. Stanley, Nag's Head Brewery, Wrexham, North Wales, Brewer.
- Smithells, Prof. A., Yorkshire College, Leeds, Professor of Chemistry.
- Smithers, F. O., Dashwood House, 9, New Broad Street, London, E.C., Chemical Agent.
- Smithson, J., Park Printworks, Halifax, Stuff Printer.
- Smithson, Saml., Ravensthorpe, near Dewsbury, Yorks, Dyer and Dyersalter.
- Snape, Dr. H. Lloyd, University College, Aberystwith, Professor of Chemistry.
- Snowdon, Charlie, 269, West Ferry Road, Millwall, E., Chemical Works Manager.
- Snowdon, Jno., jun., Messrs. Snowdon, Sons, & Co., Millwall, E., Chemical and Oil Manufacturer.
- Soames, J. K., Thames Soap and Candle Works, Greenwich, S.E., Soap and Candle Manufacturer.
- Sohn, Chas. E., 22, Southampton Row, London, W.C., Analyst.
- Solvay, Armand, 25, Rue Prince Albert, Brussels, Gérant de la Société Solvay et Cie.
- Solvay, Ernest, 43, Rue des Champs Elysées, Brussels, Alkali Manufacturer.
- Sommer, Adolf, corner 1st and Binney Streets, East Cambridge, Boston, Mass., U.S.A., Pharmaceutical Chemist.
- Sonstadt, Edw., Church Fields, Cheshunt, Herts, Chemical Technologist.
- Sorel, Ernest, 93, Avenue d'Orleans, Paris, Engineer.
- Souther, H., Dept. of Tests, Pope Manufacturing Co., Hartford, Conn., U.S.A., Chemical and Metallurgical Engineer.
- Southern, Thos., Jr. Jr., Wheatthill Chemical Works, St. Simon Street, Salford, Manufacturing Chemist.
- Soward, A. W., 28, Therapia Road, Honor Oak, S.E., Principal Clerk (Legacy Duty Office).
- Sowerby, Thos. H., Sherwell, Dartmouth Place, Blackheath, S.E., Soap Manufacturer.
- Sowerby, W. M., 12, Upper Queen's Terrace, Fleetwood, Lancashire, Alkali Works Manager.
- Sowler, Alf., Coolgardie, W. Australia, Assayer.
- Spackman, Chas., Rosehaugh, Clitheroe, Lancashire, Portland Cement Manufacturer.
- Speakman, J. J., Stanley Villas, Greenway Road, Runcorn, Chemical Works Clerk.
- Spence, D., Alum Works, Manchester, Alum Manufacturer.
- Spence, F., Alum Works, Manchester, Alum Manufacturer.
- Spence, J. Napier, Heathfield, Harrow-on-the-Hill, Teacher of Chemistry.
- Spence, J. W., 58, Dobbie's Loan, Glasgow, Drysalter.
- Spencer, Jno., Globe Tube Works, Wednesbury, Tube Manufacturer.
- Spencer, J. W., Newburn, Newcastle-on-Tyne, Steel Manufacturer.
- Spiegel, Dr. Adolf, Messel, bei Darmstadt, Germany, Analytical Chemist.
- Spies, Adolph, 102, Fenchurch Street, London, E.C., Chemical Merchant.
- Spies, Hermann, 102, Fenchurch Street, London, E.C., Chemical Merchant.
- Spiller, A., Oldbury Villa, Southbury Road, Enfield, Electrician.
- Spiller, J., 2, St. Mary's Road, Canonbury, London, N., Consulting Chemist.
- Spoor, J. L., Madras Cement Works, Madras, India, Portland Cement Manufacturer.
- Sprengel, Hermann Johann Philipp, Ph.D. (Heidelb.), F.R.S., Royal Prussian Professor (titular), Savile Club, 107, Piccadilly, London, W., Chemist.
- Squire, P. W., 413, Oxford Street, London, W., Pharmaceutical Chemist.
- Squire, Dr. W. S., Clarendon House, St. John's Wood Park, N.W., Chemical Engineer.
- Stacey, H. G., 300, High Holborn, London, W.C., Manufacturing Chemist.
- Stafford, Chas. H., c/o The Birkacre Printing Co., Birkacre, Chorley, Colourist.
- Stahl, Dr. K. F., 57th Street and A. V. Ry., Pittsburgh, Pa., U.S.A., Chemical Works Manager.
- Stanford, E. C. C., Glenwood, Dalnair, N.B., Chemical Manufacturer.
- Stanger, W. Harry, Broadway Testing Works, Westminster, S.W., Engineer.
- Stanley, C. L., c/o Chas. Stanley and Son, Wath, via Rotherham, Oleic Acid Manufacturer.
- Stanning, John, Broadfield, Leyland, near Preston, Bleacher.
- Stantial, Frank G., c/o Cochrane Chemical Co., Everett, Mass., U.S.A., Technical Chemist.
- Staples, H. J., Spendon, Derby, Colour Manufacturer.
- Staples, Sir Nath. A., Bart., Lissan, Cookstown, Ireland.
- Stark, J. F., 31, Highfield South, Rock Ferry, near Birkenhead, Works Manager (Price's Patent Candle Co.).
- Starling, J. H., 32, Craven Street, Strand, London, W.C., Analytical Chemist.
- Statham, Noel, Penny Lane Farm, Cronton, Prescott, Lancashire, Engineer.
- Stead, J. Christopher, Mitre Works, Cordova Road, Bow, E., Chemist and Manager.
- Stead, J. E., 11, Queen's Terrace, Middlesbrough-on-Tees, Analytical Chemist.
- Stead, W. H., 23, Boundary Street, Liverpool; and (Journals) Orchard Place, Blackwall, E., Oil Refiner.
- Stearns, Fred. K., Detroit, Mich., U.S.A., Manufacturing Chemist.
- Stebbins, J. H., 114, Pearl Street, New York, U.S.A., Analytical Chemist.
- Steedman, H. R., Goltyn, Carrick Road, Ayr, N.B., Chemical Manufacturer.

- Steel, Fred. W., c/o Fiji Sugar Co., Ltd., Tamana, Navua River, Fiji, Analytical Chemist.
- Steel, R. Elliott, Northampton and County School, Northampton, Headmaster.
- Steel, Thos., Colonial Sugar Refinery, Sydney, N.S.W., Sugar Chemist.
- Steinhart, Dr. Oscar L., 4, Palace Street Mansions, Buckingham Gate, S.W., Manufacturing Chemist.
- Stenhouse, T., Townhead, Rochdale, Analytical Chemist.
- Stephens, Alfred, Dinas Silica Works, Kidwelly, South Wales, Manager.
- Stephens, Daniel, The Arlais, Kidwelly, South Wales, Silica Manufacturer.
- Stephens, H. O'Reilly, 191, Aldersgate Street, London, E.C., Writing Ink Manufacturer.
- Stephens, M. E., Avenue House, Finchley, N., Ink Manufacturer.
- Stephens, H. Chas., M.P., Avenue House, Finchley, N., Ink Manufacturer.
- Stern, Arthur L., 170, Ashby Road, Barton-on-Trent, Brewing Chemist.
- Stewart, D. R., Broxburn, near Edinburgh, N.B., Oilworks Chemist.
- Stevens, Jno. H., 295, Ferry Street, Newark, N.J., U.S.A., Manufacturing Chemist.
- Stevens, Wm., The Native Guano Co., Ltd., 29, New Bridge Street, Blackfriars, E.C., Secretary.
- Stevens, W. J., Rathmines, Brecknock Road, Knowle, Bristol, Technical Chemist.
- Stevenson, Jas., 23, West Nile Street, Glasgow; and The Broomfields, Largs, N.B., Manufacturing Chemist.
- Stevenson, J. C., Alkali Manufacturer.
- Stevenson, Dr. T., Guy's Hospital, London, S.E., Chemical Lecturer.
- Stevenson, W., Standard Works, 95A, Southwark Street, London, S.E., Chemical Manufacturer.
- Stewart, Alex. F., Central Assay Office, Boksburg, S.A.R., Assayer.
- Stewart, Ebenezer, Oil Seed Mills, Rochester, Kent, Seed Crusher.
- Stewart, Jeffrey, 35, Argyle Road, Ilford, Essex, Sugar Works Manager.
- Stewart, Robt., c/o Boake, Roberts, and Co., Warton Road, Stratford, E., Chemical Works Manager.
- Stewart, R. Patrick, 21, Industry Place, Kirkintilloch, N.B., Analytical Chemist.
- Stewart, S., c/o Michael Nairn and Co., Ltd., Linoleum Works, Kirkecuddy, N.B., Technical Chemist.
- Stiebel, G. L., Graskop Ltd., Pilgrim's Rest, S.A.R., Manager.
- Stillman, Dr. T. B., Stevens Institute of Technology, Hoboken, N.J., U.S.A., Professor of Analytical Chemistry.
- Stillwell, Chas. M., 55, Fulton Street, New York, U.S.A., Analytical and Consulting Chemist.
- Stirk, Jos., Ferncliffe, Elm Bank, Nottingham, Brewer's Engineer.
- Stock, F. W., Keating, Birchfield, Darlington, Analytical and Consulting Chemist.
- Stockdale, Albert, c/o R. Dewhurst and Co., Ltd., Birstall, near Leeds, Printer.
- Stockdale, Wm., Irwell Printworks, Stacksteads, near Manchester, Calico Printer.
- Stocks, H. B., c/o Messrs. Day and Martin, Borough Road, London, S.E., Analytical Chemist.
- Stoddart, F. Wallis, Western Counties Laboratory, Bristol, Analytical Chemist.
- Stoer, J., 6, Hanover Quay, Dublin.
- Stoker, G. N., Laboratory, Somerset House, London, W.C., Analytical Chemist.
- Stone, Frank, Laboratory, Department of Mines and Water Supply, Spencer Street, Melbourne, Victoria, Analytical Chemist and Assayer.
- Stone, F. B., Eardley Villa, Picardy Hill, Belvedere, Kent, Technical Chemist.
- Stone, Thos. W., Chemical Works, St. George, Bristol, Chemical Manufacturer.
- Storer, Dr. John, 29, Bigh Street (G.P. Box 220), Sydney, New South Wales, Consulting Chemist.
- Storey, I. H., Haverbreaks, Lancaster, Chemical Manufacturer.
- Stowe, W. T., Inland Revenue, Wellington, Salop, Analytical Chemist.
- Strangman, J. Pim, Bleacher.
- Strong, Colin R., 18, Exchange Street, Manchester, Oil Merchant.
- Stuart, C. E., 29, Mosley Street, Newcastle-on-Tyne, Chemical Apparatus Dealer.
- Stuart, Harry T. R., Ashbank, Thornliebank, Glasgow, Printworks Sub-Manager.
- Stuart, Jas., 22, High Street, Hull, Seed Crusher and Oil Refiner.
- Stuart, T. W., 7, Livingston Drive, Sefton Park, Liverpool, Alkali Works Manager.
- Stubbs, Augustus J., 1, Calle de Luchana, Madrid, Spain, Mining Engineer.
- Studer, Dr. A., 10, Marsden Street, Manchester, Consulting Chemist.
- Studer, Simon J., 17, Lovely Lane, Warrington, Technical Chemist.
- Suckert, Dr. J. J., 253, Broadway, New York City, U.S.A., Manufacturing Chemist.
- Sulborough, Dr. J. J., University College, Nottingham, Lecturer in Chemistry.
- Salman, H. L., 69, Gracechurch Street, London, E.C., Chemist and Metallurgist.
- Summers, Bertrand S., c/o The Western Electric Co., 227, South Clinton Street, Chicago, Ill., U.S.A., Electro-Chemist.
- Summer, Harold, Batt Hill, Prestwich, Manchester, Dyer and Bleacher.
- Sunderland, A., Hainworth Wood Road, Ingrow, Keighley, Teacher of Chemistry.
- Sundström, Karl J., Trenton, Wayne Co., Mich., U.S.A., Manufacturing Chemist.
- Sutherland, D. A., 28, Victoria Street, Westminster, S.W., Consulting Technical Chemist and Assayer.
- Sutherland, Geo., Croft Cottage, Bonhill, N.B., Chemist.
- Sutherland, Jas., c/o British Aluminium Co., Ltd., Larne Harbour, Co. Antrim, Ireland, Chemist.
- Sutherland, R. M., Lime Wharf Chemical Works, Falkirk, N.B., Chemical Manufacturer.
- Sutton, F., London Street, Norwich, Analytical Chemist.
- Sutton, F. Napier, 6, Grosvenor Gardens, Willesden Green, N.W., Alkali Works Inspector.
- Swan, David, The Swan Colour Co., Ltd., Petershill Road, Glasgow, Colour Manufacturer.
- Swan, J. Cameron, 4, Nicholas Buildings, Newcastle-on-Tyne, Manufacturing Chemist.
- Swan, J. W., 58, Holland Park, London, W., Chemist and Electrician.
- Swinburne, Geo., c/o J. Coates & Co., Planet Chambers, 8, Collins Street East, Melbourne, Australia; (subs.) Suffolk House, Laurence Pountney Hill, E.C., Gas Engineer.
- Swinsee, John A., c/o The Irish National Condensed Milk Co., Ltd., Clonmel, Ireland, Technical Chemist.
- Sykes, James, Springfield Soapworks, Heckmondwike, Soap and Chemical Manufacturer.
- Syme, W. B., c/o Young's Paraffin Oil Co., Addiewell, West Calder, N.B., Oil Works Chemist.

## T

- Taylor, G. W., Dinting Vale Printworks, Dinting, near Manchester, Printworks Chemist.
- Taylor, H. E., c/o Matthews' White Lead Co., Ltd., Hebburn-on-Tyne, Lead Works Manager.
- Taylor, Jas., Department of Mines, Sydney, N.S.W., Government Metallurgist.
- Taylor, Jas. Davis, 9, Mincing Lane, London, E.C., Chemical Merchant.
- Taylor, J. Scott, c/o Winsor and Newton, Limited, 38, Rathbone Place, London, W., Technical Chemist.
- Taylor, Martin, Ingersley, Palmerston Road, Buckhurst Hill, Essex, Chemical Works Manager.
- Taylor, Thos., Walmerley Bleach and Dyeworks, near Bury, Lancashire, Bleacher and Dyer.
- Taylor, W. Ambrose, Madron, Penzance, Cornwall, Chemical Apparatus Maker.
- Taylor, W. G. H., 56, Meanley Road, Manor Park, Essex, Analytical Chemist.
- Taylor, W. J., 55, Forsyth Street, Greenock, N.B., Technical Chemist.
- Tchaykovsky, N. W., Langham House, Harrow-on-the-Hill, Consulting Chemist.
- Teauby, G. W. A., Laboratory, 65, Bath Row, Birmingham, Analytical Chemist.
- Teed, Dr. F. L., 15, Victoria Street, Westminster, London, S.W., Analytical Chemist.
- Tennant, Sir Chas., Bart., 35, Grosvenor Square, S.W.; and Glen, Peebleshire, N.B. (Journals to St. Rollox, Glasgow), Alkali Manufacturer.
- Tennant, Jas., Dartmouth Lodge, Saltwell, Gateshead-on-Tyne, Alkali Manufacturer.
- Tennille, Geo. F., 77, Carnegie Avenue, East Orange, N.J., U.S.A., Chemist (Central Lard Co.).
- Terry, Albert, Verulam, Mount Albert Road, Balwyn, near Melbourne, Victoria, Brewer.
- Terry, Hubert L., 14, Herbert Street, Moss Side, Manchester, Technical Chemist.
- Tervet, R., 54, Pen-hurst Road, South Hackney, E., Oil Works Manager.
- Tetley, C. F., Messrs. Jos. Tetley and Son, The Brewery, Leeds, Brewer.
- Thackray, R. B., Leather Works, Newlay, Leeds, Leather Manufacturer.
- Thew, Walter H., Talbot House, Arundel Street, Strand, W.C., Director.
- Thomas, C., Pitch and Pay, Stoke Bishop, near Bristol, Soap Manufacturer; Deputy Chairman, Midland Railway.
- Thomas, H. Russell, Broad Plain Soap Works, Bristol, Soap Manufacturer.
- Thomas, J., Brook House, Wooburn, near Beaconsfield, Paper Maker.
- Thomas, J. W., Drumpellier, Brunswick Road, Gloucester, Analytical Chemist.
- Thomas, R. Schofield, 4, South Road, Handsworth, Staffordshire, Chemical Merchant.
- Thomas, S. Percy, 105, Clova Road, Forest Gate, E., Technical Chemist.
- Thomasson, Wm., 167, North Road, St. Helens, Lancashire, Chemist.
- Thompson, Prof. Claude M., University College, Cardiff, Professor of Chemistry.
- Thompson, G. Rudd, 57, Dock Street, Newport, Mon., Analytical and Consulting Chemist.
- Thompson, Gustave W., c/o National Lead Co., Marshall Street, Brooklyn, N.Y., U.S.A., Chemist.
- Thompson, W., jun., Larkfield, Earlestown, Lancashire, Sugar Refiner.
- Thompson, W. G., Tonge Springs Works, Middleton, near Manchester, Colour Manufacturer.
- Thompson, W. P., Patent Office, 6, Lord Street, Liverpool, Patent Agent.
- Thomsen, Alonzo L., 16, West Madison Street, Baltimore, Md., U.S.A., Manufacturing Chemist.
- Thomson, Dr. Andrew, 10, Pitcullen Terrace, Perth, Chemical Lecturer.
- Thomson, G. Carruthers, 23, Kersland Terrace, Hillhead, Glasgow, Engineer.
- Thomson, Jas. M., Royal Gunpowder Factory, Waltham Abbey, Essex, Manager (Cordite Branch).
- Thomson, John, The Grange, Buckton Vale, Stalybridge, Printworks Manager.
- Thomson, J. S., c/o Messrs. Grieve and Co., West Tower Street, Carlisle, Technical Chemist.
- Thomson, Robt. T., 156, Bath Street, Glasgow, Analytical Chemist.
- Thomson, W., Royal Institution, Manchester, Analytical and Consulting Chemist.
- Thomson, Wm. Thos., Royal Gunpowder Factory, Waltham Abbey, Essex, Explosives Chemist.
- Thorne, Dr. L. T., 8, Dynevor Road, Richmond-on-Thames; and (Journals) Southampton Wharf, Battersea, S.W., Technical Chemist.
- Thornycroft, Wallace, 140, Hope Street, Glasgow, Technical chemist.
- Thornton, Christopher, Allen's Printworks, Providence, R.I., U.S.A., Printworks Manager.
- Thornton, David H., Brookfoot Dyeworks, Brighouse, Yorks, Dyer.
- Thornton, H., 5, George Street, Euston Road, N.W., Analytical Chemist.
- Thorp, Frank H., Mass. Inst. of Technology, Boston, Mass., U.S.A., Instructor in Industrial Chemistry.
- Thorpe, Dr. T. E., F.R.S., Government Laboratory, Somerset House, W.C.; and (Journals) 61, Ladbroke Grove, Notting Hill, W., Chief Chemist (Customs and Inland Revenue).
- Thorp, W., 28, Victoria Street, Westminster, S.W.; and (Journals) 24, Crouch Hall Road, Crouch End, N., Consulting Chemist.
- Tilden, Prof. W. A., F.R.S., 9, Ladbroke Gardens, Notting Hill, W., Professor of Chemistry.
- Tinmins, A., Argyll Lodge, Higher Runcorn, Civil Engineer.
- Tinms, T. Sutton, Widnes, Chemical Manufacturer.
- Tinsley, John D., Miller School, Crozet, Va., U.S.A., Professor of Chemistry.
- Tipler, Fred. C., 7, Richard Street, Crewe, Analytical Chemist.
- Tobey, C. H., Collingwood, Ontario, Canada, Tannery Chemist.
- Toch, Maximilian, c/o Toch Bros., 468-472, West Broadway, New York City, U.S.A., Chemist.
- Tocher, Jas. F., 1, Chapel Street, Peterhead, N.B., Pharmaceutical Chemist.
- Todd, A. M., 204, North Rose Street, Kalamazoo, Mich., U.S.A., Manufacturing Chemist.
- Toms, F. Woodland, States Analyst's Office, St. Heliers, Jersey, Analytical Chemist.
- Tonkin, John, 25A, East 34th Street, Bayonne City, N.J., U.S.A., Manufacturing Chemist.
- Tonks, E., Packwood, Knowle, near Birmingham, Brass Founder.
- Tothill, M. A. L., Castle and Buitengracht Streets, Cape Town, S. Africa, Manufacturing Chemist.
- Towers, J. W., Brantwood, Allerton, near Liverpool, Analytical Chemist.
- Towner, Rev. Geo., Head Master of Organised Science School.
- Townsend, Chas. F., 31, Elms Road, Clapham Common S.W., Chemist.

- Townsend, Chas. W., 19, Crawford Street, Port Dundas, Glasgow, Chemical Manufacturer.
- Townsend, Oliver C., Port Dundas, Glasgow, Chemical Manufacturer.
- Traphagen, Dr. Frank W., Montana Agricultural Experimental Station, Bozeman, Mont., U.S.A., Chief Chemist.
- Travers, Morris W., 2, Phillimore Gardens, Kensington, W., Chemist.
- Trechmann, A. O., Tinnoth House, Cuxton, near Rochester, Cement Works Chemist.
- Trechmann, Dr. C. O., Warren Cement Works, Hartlepool, Cement Manufacturer.
- Treharne, F. Gwilym, Wrangbrook, Llanishen, near Cardiff, Analytical Chemist.
- Trench, G., Standard House, Faversham, Kent; and the Cotton Powder Co., Limited, Faversham, Explosives Works Manager.
- Trewby, Herbert, Radnor House, Ribblesdale Road, Hornsey, N., Analytical Chemist.
- Tribe, P. C. M., Oswego, New York, U.S.A., Secretary.
- Trimble, Prof. H., 145, North 10th Street, Philadelphia, U.S.A., Professor of Chemistry.
- Trobridge, A., c/o Oldbury Alkali Co., Ltd., Oldbury, Birmingham, Technical Chemist.
- Trubshaw, Wolstan, 6, St. Benet Place, London, E.C., Mining Agent.
- Truby, Charles, 20, High Street, Manchester, Chemical Manufacturer.
- Tsukiyama, S., Nippon Seito Kaisha, Osaka, Japan, Paper Mills Chemist.
- Tucker, Alex. E., 35, Paradise Street, Birmingham, Metallurgist and Chemist.
- Tucker, Prof. G. R., City Hospital, Boston, Mass., U.S.A., Professor of Chemistry (Massachusetts College of Pharmacy).
- Tuer, Arthur H., Thornhill, near Wigan, Analytical Chemist.
- Tulloch, John, 11, Newton Terrace, Hebburn-on-Tyne, Analytical Chemist.
- Turnbull, G. W., 35, Lancaster Road, Carnforth, Lancashire, Metallurgical Chemist.
- Turnbull, Wm., 14, Wilberforce Terrace, Gateshead-on-Tyne, Manufacturing Chemist.
- Turnbull, W. S., Place of Bonhill, Renton, Dumbartonshire, Chemical Manufacturer.
- Turner, H. B. H., 4, Calverley Terrace, Tnubridge Wells, Sugar Refiner.
- Turner, Thos., Ravenhurst, Rowley Park, Stafford, Metallurgist and Director of Technical Education.
- Turney, Sir J., Springfield, Alexandra Park, Nottingham, Tanner.
- Turri, Geo. G., Sun Buildings, Queen Street, Melbourne, Victoria, Patent Agent.
- Tuthill, Jos. B. T., Salem Gas Light Co., Salem, Oregon, U.S.A., Chemist.
- Tweedy, Jas., 306A, Burdett Road, Limehouse, E., Metallurgical Chemist.
- Twitchell, E., 10, Bellevue Avenue, Mount Auburn, Cincinnati, Ohio, U.S.A., Candle Works Manager.
- Twynan, T., Elmhurst, Egham Hill, Surrey, Metallurgist.
- Type, P. G. W., Ravenhurst, Norbiton Park, New Malden, Surrey, Chemical Manufacturer.
- Tyrer, A. J., 3, Norwich Road, Forest Gate, E.; and (Journals) Marbacherweg 29, Marburg a/d Lahn, Germany, Chemical Student.
- Tyrer, Chas. T., Stirling Chemical Works, Stratford, E., Manufacturing Chemist.
- Tyrer, T., Stirling Chemical Works, Stratford, E., Chemical Manufacturer.
- Uhlig, E. C., c/o Whittall, Tatum, and Co., 48, Barclay Street, New York, U.S.A., Glass Works Chemist.
- Ullman, Jas. A., c/o Jaenecke-Ullman Co., 536-538, Pearl Street, New York City, U.S.A., Chemist and Superintendent (Printing Ink Works).
- Ullmann, Dr. Sabbati E., 167, West 85th Street, New York, U.S.A., Manufacturing Chemist.
- Umney, C., 50, Southwark Street, London, S.E., Manufacturing Chemist.
- Underhill, Thos. J., H.M. Victualling Yard, Deptford, S.E., Assistant Inspector of Stores.
- Underwood, G. R., Box 460, Peabody, Mass., U.S.A., Glue Works Chemist.
- Urquhart, David, 17, Victoria Street, Westminster, S.W., Electrical Engineer.
- Usmar, J. H., 22, Billiter Street, London, E.C., Chemical Merchant.

## V

- Van der Linde, Harold, 61, Front Street West, Toronto, Canada, Chemist (India-rubber and Gutta-percha Manufacturing Co.).
- Vanderpoel, Dr. Frank, 191, Roseville Avenue, Newark, N.J., U.S.A., Chemist.
- Van Gundy, Chas. P., Laboratory, B. & O. R. R., Baltimore, Md., U.S.A., Metallurgical Chemist.
- Van Ingen, Dudley A., 135, Henry Street, Brooklyn, N.Y., U.S.A., Chemist.
- Van Laer, Norbert, Black Eagle Brewery, Burton-on-Trent, Brewer's Chemist.
- Vargas-Vergara, J. M., Apartado No. 237, Bogota, Republic of Colombia, S. America, Metallurgical Chemist.
- Vasey, T. E., 6, South Parade, Leeds; Journals to P.O. Box 1449, Montreal, Canada, Chemical Engineer.
- Vaughan, J. L., 2, Christie Road, South Hackney, E., Chemical Works Manager.
- Vautin, Claude T. J., 28, Basinghall Street, London, E.C., Metallurgist.
- Veitch, Geo., Chemical Works, Crieff, N.B., Manufacturing Chemist.
- Veitch-Wilson, J., Wadhurst, Culverden Road, Balham, S.W., Oil Refiner.
- Verel, W. A., 136, West George Street, Glasgow.
- Vickers, W., Rose Hill, Smedley Lane, Manchester, Chemical Manufacturer.
- Vigelius, Carl, 175, Pearl Street, New York City, U.S.A., Shellac Bleacher.
- Vincent, Jos. A., 309, Bullitt Building, Philadelphia, Pa., U.S.A., Mechanical Engineer.
- Voelcker, E. W., 22, Tudor Street, London, E.C., Agricultural Chemist.
- Voelcker, Dr. J. A., 20, Upper Phillimore Gardens, Kensington, W., Agricultural Chemist.
- Vogel, Julius L., Hillersdon, East Molesey, Surrey, Engineer.
- Vorster, Fritz, Cöln-Marienburg, Germany, Manufacturing Chemist.
- Voss, Hermann, 19, Beckenham Road, Beckenham, Kent, Manure Works Manager.
- Vulté, Dr. Hermann T., School of Mines, Columbia College, New York, U.S.A., Analytical Chemist.

## W

- Waché, Alf., 27, Rue Morel, Douai, France, Caustic Potash Manufacturer.
- Wachtel, Gregory, 6, Manejuy Pereulok, St. Petersburg, Russia, Chemical Engineer.
- Waddington, Thos. W., 8, Albert Street, Padiham, Lancashire, River Inspector.
- Wade, Jas. L., 28, West Kensington Gardens, London, W., Chemical Manufacturer.
- Wade, John, Wyvenhoe, Purley, Surrey, Demonstrator of Chemistry.
- Wade, W. L., 28, West Kensington Gardens, W., and (Journals) Staines Linoleum Works, Staines, Chemist.
- Wadman, W. E., 102, Lord Avenue, Bayonne, N.J., U.S.A., Manufacturing Chemist.
- Wagner, W. G., Glyndhurst, Ealing Common, W., Analytical and Consulting Chemist.
- Wainwright, Dr. J. H., 22, West 46th Street, New York, U.S.A., Analytical Chemist.
- Wainwright, Wm., c/o Dublin and Wicklow Manure Co., Lim., Ballybough, Dublin, Chemist.
- Waldman, Louis J., P. O. Box 162, Albany, N.Y., U.S.A., Aniline Dye Manufacturer.

## U

- Waldstein, Dr. Martin E., 41, Trinity Place, New York, U.S.A., Manufacturing Chemist.
- Walker, Archibald, 8, Crown Terrace, Glasgow, Distiller.
- Walker, E. Robinson, 18, St. Ann's Street, Manchester, Patent Agent.
- Walker, Dr. Jas., University College, Dundee, Professor of Chemistry.
- Walker, S. R., 19, Wolsey Street, Radcliffe, Manchester, Foreman Dyer.
- Walker, T., Eccleston Park, Prescott, Lancashire, Chemical Manufacturer.
- Walker, W. Sloane, c/o Walker, Ltd., Litherland, near Liverpool, Tanner.
- Wallace, Robert, 1, Coates Place, Edinburgh, Distiller.
- Waller, Dr. E., 449, First Avenue, New York, U.S.A., Professor of Chemistry.
- Walsh, P. T., Hamilton Printworks, Lowell, Mass., U.S.A., Colour Printer.
- Walsham, T., Brewery, Stockwell, London, S.W., Brewer.
- Walton, E., 114, Holborn, E.C., Inventor and Manufacturer.
- Wander, Dr. A., Chemical Laboratory, Berne, Switzerland, Chemist.
- Want, W. Philip, 42, Bi-shopsgate Street Without, London, E.C., Pharmacist and Editor.
- Warburton, Thos., Clayton Aniline Co., Ltd., Clayton, Manchester, Chemist.
- Ward, G., Messrs. Hirst, Brooke and Hirst, Leeds, Chemical Works Manager.
- Ward, G. J., The Cottage, Hallam Fields, near Nottingham, Civil Engineer.
- Ward, Howard Chas., Yeaton, Hordle, Lymington, Hants, Deputy Chairman of Gas Co.
- Ward, Thos., Wadbrook House, Northwich, Salt Manufacturer.
- Wardale, J. D., Redheugh Engine Works, Gateshead-on-Tyne, Engineer.
- Warden, Dr. C. J. H., Medical College, Calcutta, India, Professor of Chemistry.
- Warden, Jno. B., c/o Cassel Gold Ext. Co., Ltd., Vancouver, British Columbia, Analytical Chemist.
- Wareing, Arthur E., Bedford House, Appleton, Widnes, Analytical Chemist.
- Warington, Robt., F.R.S., Harpenden, Herts, Agricultural Chemist.
- Warner, H. G., 13, Disraeli Road, Forest Gate, Essex, Chemical Engineer.
- Warren, Fiske, 220, Devonshire Street, Boston, Mass., U.S.A., Paper Manufacturer.
- Warren, Jno. Davis, 7, Essex Road, Acton, W., Manufacturing Chemist.
- Warren, T. T. P. Bruce, Tamworth Villa, Earham Grove, Forest Gate, Essex, Analytical Chemist.
- Warwick, A. W., The Ninal Mine, Wickes, Montana, U.S.A., Metallurgical Chemist.
- Watel, H. G., Buckhurst Hill, Essex, Consulting Mechanical Engineer.
- Waterfall, W. B., c/o Avon Manure Co., Bristol; and (Journals) Thirlmere, Clavering Road, Redland, Bristol, Manure Manufacturer.
- Waterhouse, Colonel Jas., 14, Wood Street, Calcutta, India, Assistant Surveyor-General of India.
- Waterhouse, Robt., 101, Leadenhall Street, London, E.C., Analytical and Agricultural Chemist.
- Wates, Edw. A., Comorandel G. M. Co., Oorgaum, Mysore, India, Metallurgical Chemist.
- Watmough, B., Upper Regent Street, Belle Vue, Wakefield, Analytical Chemist.
- Watson, Alex. Forbes, St. James' Gate, Dublin, Chemist.
- Watson, Chas. Ernest, c/o Peter Spence and Sons, Manchester Alum Works, Manchester, Chemical Assistant.
- Watson, C. Heron, Bullionfield Paper Mill, by Dundee, N.B., Paper Manufacturer.
- Watson, Chas. S., P.O. Box 27, Charters Towers, Queensland, Analytical Chemist.
- Watson, Chas., 36-40, Hewitt Street, Gaythorn, Manchester, Manufacturing Chemist.
- Watson, D., Willow Bank House, Kersal Vale, Manchester, Metallurgist.
- Watson, Eric E., Fundicion y Beneficiadora, Antofagasta, Chili, Metallurgical Chemist.
- Watson, G., 16, East Nelson Street, Whitevale, Glasgow, Manufacturing Chemist.
- Watson, Geo. P., Elm Lodge, Halliwell Lane, Cheetham Hill, Manchester, Printworks Chemist.
- Watson, Jas., 48, West Park Terrace, South Shields, Alkali Works Manager.
- Watson, Jno. C., c/o Daniel Lee & Co., Castleton, Manchester, Technical Chemist.
- Watson, Jno., Cement Works, Gateshead-on-Tyne, Cement Manufacturer.
- Watson, Jno., P.O. Box 317, Johannesburg, S.A.R., Technical Chemist.
- Watson, Jno., 8, Newman Street, Victoria Docks, E., Analytical Chemist.
- Watson, John, 30, Bolan Street, Battersea, S.W., Science Student.
- Watt, A., 19, Brompton Avenue, Sefton Park, Liverpool, Sugar Works Chemist.
- Watts, A. J., 130, Caixa, Pernambuco, Brazil, Sugar Works Chemist.
- Watts, Chas. W., 49, Goldhurst Terrace, London, N.W., Gasworks Chemist.
- Watts, Jno. Isaac, Fairleigh, Hartford, Cheshire, Alkali Works Manager.
- Webb, Saml. G., 2314, East Grace Street, Richmond, Va., U.S.A., Technical Chemist.
- Webb, Wm. Hubert, Randalstown, co. Antrim, Ireland, Linen Manufacturer.
- Weber, Dr. C. Otto, 2, Randolph Street, Crumpsall, Manchester, Analytical Chemist.
- Webster, C. S., Stanford, Malvern House, Redland, Bristol, Professor of Chemistry.
- Weeks, H. B., Cossipore, Calcutta, India, Analytical Chemist.
- Weems, Dr. J. B., Iowa Agricultural College, Ames, Iowa, U.S.A., Agricultural Chemist.
- Weicker, Theodore, c/o Merck and Co., New York, U.S.A., Chemical Manufacturer.
- Weightman, Alf. T., Chloride Electrical Storage Syndicate, Clifton Junction, near Manchester, Electro-Chemist.
- Weightman, John F., c/o Powers & Weightman, Philadelphia, Pa., U.S.A., Doctor of Medicine.
- Weir, Surgeon-Colonel P. A., c/o Messrs. King, King, and Co., Bombay, India, Surgeon.
- Welch, J. Cuthbert, The Brewery, Reading, Berks, Brewer's Chemist.
- Welch, Thos., Green Vale Printworks, Westhoughton, Lancashire, Calico Printer.
- Weldon, Ernest, Egypt Road, New Basford, Nottingham, Dyer.
- Wells, G. I. J., 77, Parkgate Road, Chester, Analytical Chemist.
- Wells, Jas. Gray, Selwood House, Shobnall Street, Burton-on-Trent, Brewing Chemist.
- Wells, Dr. Jas. S. Chester, P.O. Box 95, Hackensack, N.J., U.S.A., Instructor in Analytical Chemistry.
- Wells, Pierson L., 86, Joralemon Street, Brooklyn, N.Y., U.S.A., Patent Lawyer and Engineer.
- Welsh, Jas., Horrocks Lane Dyeworks, Red Bank, Manchester, Printworks Manager.
- Welsh, Thos. L., 3, Prince's Gardens, Dowanhill, Glasgow, Analytical Chemist.
- Welsh, W., Holt Town, Manchester.
- Werner, Emil A., 5, Church Avenue, Rathmines, Dublin, Chemical Demonstrator.
- Wessel, Carl, Bernburg, Anhalt, Germany, Alkali Manufacturer.
- Wesson, D., c/o The Wesson - Nivison Manufacturing Co., Cortlandt, N.Y., U.S.A., Consulting Technical Chemist.
- Westenfelder, B. D., c/o American Oak Leather Co., Cincinnati, Ohio, U.S.A., Leather Chemist.
- Westmoreland, J. W., 2, City Road, Finsbury Square, E.C., Metallurgical Chemist.
- Weston, Robt. S., Box 614, Louisville, Ky., U.S.A., Technical Chemist.
- Weston, Wm., H.M. Dockyard, Portsmouth, Analytical Chemist.
- Wetter, Jasper, 433, Strand, London, W.C., Patent Agent.
- Wetzel, H. A., Box 470, Detroit, Michigan, U.S.A., Manufacturing Chemist.

- Whalley, L. J. de, 26, Park Place, Greenwich, S.E., Sugar Chemist.
- Wheelwright, Dr. E. W., The Oaklands, Warley, Oldbury, near Birmingham.
- Whiffen, T., Lombard Road, Battersea, London, S.W., Manufacturing Chemist.
- Whiffen, Thos. J., Harefield, Southfields, S.W., Manufacturing Chemist.
- Whiden, W. G., Lombard Road, Battersea, London, S.W., Manufacturing Chemist.
- Whitaker, Alf. Waltaire, Horsforth, Leeds, Dyer.
- Whitaker, H. L., Condong Sugar Mill, Tweed River, New South Wales, Sugar Chemist.
- Whitaker, Thos., Newlay Hall, near Leeds, Dyer.
- Whitaker, Thorp, Messrs. E. Ripley and Sons, Bradford, Yorks, Dyer's Chemist.
- White, A. D., Avenue House, West Drayton, Middlesex, Chemical Manufacturer.
- White, Arthur F., 61, Sunbridge Road, Bradford, Yorks, Manufacturing Druggist.
- White, B. Newport Manor Hill, Marple, Cheshire, Consulting Brewer.
- White, Henry, 43, Woodstock Road, Sheffield, Manufacturing Chemist.
- White, Jno. Freebairn, c/o Panjom Mining Co., Panjom-Pahang, via Singapore, Chemist.
- White, Jos. Walwyn, Springfield, Farnworth, nr. Widnes, Iron Merchant.
- White, J. Campbell. See Overtoun, Lord.
- White, P. T., Castle Street, Saffron Hill, London, E.C., Chemical Manufacturer.
- White, W. Gilchrist, P.O., Broadbottom, near Manchester, Calico Printer's Chemist.
- White, W. H., The Cottage, Killingworth, Newcastle-on-Tyne, Chemical Manufacturer.
- White, Wm. T., Messrs. White Bros. & Co., Box 45, Lowell, Mass., U.S.A., Leather Manufacturer.
- Whitehead, J., Roach Place, Rochdale, Dyer.
- Whitehead, Wm. T., Magog, Prov. Quebec, Canada.
- Whitelaw, T. N., 87, Sydney Street, Glasgow, Soap Manufacturer.
- Whiteley, R. Lloyd, 20, Beeches Road, West Bromwich, Staffordshire, Chemical Lecturer.
- Whiteside, Jno. L., 51, Cannon Street, Bolton-le-Moors, Chemical Lecturer.
- Whittaker, C. J., Globe Chemical Works, Church, near Acerrington, Chemical Engineer.
- Whittaker, Thos., 22, Delaunays Road, Higher Crumpsall, Manchester.
- Whittle, Naylor, Newton Chemical Works, Hyde, near Manchester, Analytical Chemist.
- Whowell, F., Carr Bank, Tottington, Bury, Lancashire, Bleacher.
- Wickens, B. Foster, 83, Queen Street, Cheapside, London, E.C., Secretary and Manager (Wickens, Pease & Co., Lim.).
- Wiggin, W. W., Wiggin Street, Birmingham Heath, Birmingham, Nickel Refiner.
- Wightman, C., 1, Fenchurch Avenue, London, E.C., Chemical Merchant.
- Wileox, H., Stanford-le-Hope, Essex, Explosives Works Manager.
- Wilder, F. L., Villa Nova de Lima, Estado de Minas Geraes, Brazil, Assayer.
- Wiley, M. W., Billsdale House, York Road, West Hartlepool, Glue Maker.
- Wilkie, T. M., Nobel Co.'s Works, Stevenston, Ayrshire, N.B., Explosives Chemist.
- Wilkin, Sir Walter, K.C.M.G., Appold Street, Finsbury, E.C., Yeast Manufacturer.
- Wilkins, Charles, 40, Church Lane, Hornsey Old Church, N., Manufacturing Perfumer.
- Wilkinson, Dr. Saml., The Grove Co., Ltd., Marsh Gate Lane, Stratford, E., Analytical Chemist.
- Wilkinson, J. B., Tong Street, Dudley Hill, Bradford, Yorks, Chemical Manufacturer.
- Will, W. Watson, 1, St. Agnes Place, Kennington Park, S.E., Professor of Organic Chemistry.
- Willeox, Benjamin, 47, Lincoln's Inn Fields, London, W.C., Patent Agent.
- Willeox, Oliver, 307, Carroll Street, Brooklyn, N.Y., U.S.A., Technical Chemist.
- Willdigg, A. E., Ford Cottage, Coventry, Varnish Maker.
- Williams, D., 156, Chatham Street, Liverpool, Technical Chemist.
- Williams, David T., Brynawen, Hafod, Swansea, Chemist.
- Williams, Geo. G., 624, South 24th Street, Philadelphia, Pa., U.S.A., Analytical Chemist.
- Williams, Henry J., c/o Davenport and Williams, 161, Tremont Street, Boston, Mass., U.S.A., Chemical Engineer.
- Williams, Jno. Taylor, 2, Queen Street, Wellington, Salop, Brewer.
- Williams, Percy B., 22, Bisham Gardens, Highgate, N., Chemist.
- Williams, Rowland, Sunny Lea, Adelphi Road, Lancaster, Analytical Chemist.
- Williams, R. Greville, Simpson Hill House, Heywood, near Manchester, Colour Manufacturer.
- Williams, Seward W., 8, Brighton Avenue, East Orange, N.J., U.S.A., Pharmaceutical Laboratory Manager.
- Williams, Thos., Marie Rose G. M. Co., Ltd., Box 271, Johannesburg, S.A.R., Assayer and Manager.
- Williams, T. Howell. See Idris, T. H. W.
- Williams, Prof. W. Carleton, Firth College, and 23, Broomgrove Road, Sheffield, Professor of Chemistry.
- Williams, W. Collingwood, 68, Grove Street, Liverpool, Analytical Chemist.
- Williams, W. J., 635, Market Street, Camden, N.J., U.S.A., Analytical Chemist.
- Williams, Wm. Lloyd, Phoenix Mills, Dartford, Kent, Chemist and Manager.
- Williamson, J. Alex., c/o The British Explosives Syndicate, Ltd., Pitsea, Essex, Analytical Chemist.
- Williamson, Robt., Low Walker, Newcastle-on-Tyne, Technical Chemist.
- Wills, Samuel Day, Castle Green Colour Works, Bristol, Colour and Enamel Manufacturer.
- Willson, Thos. L., 45, Broadway, New York, U.S.A., Electrical Engineer.
- Wilson, A. Poole, National Education Offices, Marlboro' Street, Dublin, Ireland, Analytical Chemist.
- Wilson, Alf., c/o Messrs. J. and E. Sturge, 18, Wheeley's Lane, Birmingham, Manufacturing Chemist.
- Wilson, Anthony W., 20, Westcott Street, Hull, Colour Works Manager.
- Wilson, Cecil H., 31, Minna Road, Burngreave Road, Sheffield, Metallurgical Chemist.
- Wilson, C. J., 14, Old Queen Street, Westminster, S.W.
- Wilson, David, jun., Carberry, Killearn, by Glasgow.
- Wilson, Frank, The Brewery, Castle Street, Long Acre, London, W.C., Brewer.
- Wilson, G. E., The Chemical Works, Oldbury, near Birmingham, Chemical Manufacturer.
- Wilson, Jno., 28, Crosby Road, Romford Road, Stratford, E., Technical Chemist.
- Wilson, Jno., The Vines, Oxford Road, Runcorn, Chemical Engineer.
- Wilson, J. Arthur, Vale House, Piercy, Newchurch-in-Rossendale, Assistant Printworks Manager.
- Wilson, Jno. Ed., Wyddrington, Edgbaston, Birmingham, Chemical Manufacturer.
- Wilson, J. H., 6, Fenchurch Buildings, E.C., Chemical Manufacturer.
- Wilson, R. H., Egglescliffe, Yarm-on-Tees, Chemical Manufacturer.
- Wilson, Wesley Wm., Ardganagh, Ballsbridge, Dublin, Civil Engineer.
- Wilson, Dr. W. H., Presidency College, Madras, Lecturer on Physics.
- Wilson, Wm. Robt., 110, Long Acre, London, W.C., Analytical Chemist.
- Wilson, W. W., Greeman, Strathblane, near Glasgow, Analytical Chemist.
- Wilson, Wm., Journals to Delhi, India; Subscription c/o Clark, Wilson, & Co., 11, Abchurch Lane, E.C., Merchant.
- Wilton, Geo., Tar Works, Beckton, E., Tar Distiller.

- Wilton, Jno., Clydesdale, Norwich Road, Forest Gate, Essex, Candle Manufacturer.
- Wilton, Thos., Winsor House, Beckton, E., Tar Works Manager.
- Wing, J. D., 22, William St., New York, U.S.A., Merchant.
- Wingate, Hamilton M., c/o Jas. Wingate and Co., 4, North Court, Royal Exchange, Glasgow, Metallurgist.
- Wingfield, T. R., Nelson Square, Bolton, Brewer.
- Wingham, A., 112, Warwick Street, Pimlico, S.W., Metallurgical Chemist.
- Winsor, P. J., Greendale, Port Sunlight, near Birkenhead, Soap Works Manager.
- Winsloe, H., c/o Tennants & Co., Clayton, Manchester, Manufacturing Chemist.
- Winstanley, Hy., Hayfield Printing Co., Hayfield, near Stockport, Cacao Printer.
- Winstone, E. H., 2, Victoria Mansions, Victoria Street, London, S.W., Ink and Paint Manufacturer.
- Wirtz, Dr. Quirin, 28, Great Ormond Street, W.C., Consulting Chemist.
- Wibart, Jno., 39, St. Vincent Place, Glasgow, General Manager (Oakbank Oil Co., Ltd.).
- Witt, Dr. Otto N. E., Lindénallee 33, Westend, bei Berlin, Professor of Chemistry.
- Witthaus, Dr. R. A., 303, West 77th Street, New York City, U.S.A., Professor of Chemistry.
- Woltereck, Dr. H. C., 35, Wall Street, New York City, U.S.A., Consulting Chemist.
- Wood, Ebenezer, Stephenson Street, Cauning Town, E., Manufacturing Chemist.
- Wood, Jos. T., 29, Musters Road, West Bridgeford, Nottingham, Tanner.
- Wood, Robt. B., Dalquhurn Works, Renton, N.B., Dyeworks Chemist.
- Wood, Wm., 128, Chaussée de Turnhout, Antwerp, Belgium, Bleacher and Dyer.
- Wood, W. Copland, Rosshead, Alexandria, Dunbarton, shire, Turkey Red Dyer.
- Wood, W. H., 3, New Road, Halifax, Yorks, Chemist.
- Woodcock, R. C., American and Continental Sanitas Co., 636-642, West 55th Street, New York, U.S.A., Technical Chemist.
- Woodham, Kingston G., 5, Lethbridge Road, Southport, Oilworks Manager.
- Woodhead, Jas., Inglewood, Slaithwaite, near Huddersfield, Tar Distiller.
- Woodman, Dr. Durand, 80, Beaver Street, and 127, Pearl Street, New York, U.S.A., Analytical Chemist.
- Woodward, Jas., 144, Osborne Road, Forest Gate, Essex, Government Analyst.
- Woodward, W. C., Biddulph Valley Coal and Iron Works, Stoke-on-Trent, Ironmaster.
- Woodfindale, Chas. S., c/o Silver Spring Bleaching and Dyeing Co., Providence, R.I., U.S.A., Dyeworks Manager.

OF THE

# Society of Chemical Industry

## A MONTHLY RECORD

### FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 2.—VOL. XVI.]

FEBRUARY 27, 1897.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers. Single Copies (Members only) 2/6.]

## The Society of Chemical Industry.

### Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
Sir Frederick A. Abel, Bart., K.C.B., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Mnspratt	1885—1886.
David Howard	1886—1887.
James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
T. E. Thorpe, LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.

## COUNCIL FOR YEAR ENDING JULY, 1897.

**President:** Dr. Edward Schunck, F.R.S.

### Vice-Presidents:

Chas. Dreyfus.	E. C. C. Stanford.
Dr. A. Dupré, F.R.S.	G. N. Stoker.
Prof. A. K. Huntington.	Dr. T. E. Thorpe, F.R.S.
Boverton Redwood.	Prof. W. A. Tilden, F.R.S.
Sir H. E. Roscoe, F.R.S.	Thomas Tyrer.
A. Gordon Salaman.	

### Ordinary Members of Council:

George Beilby.	C. C. Hutchinson.
R. Forbes Carpenter.	Ivan Levinstein.
R. Le Neve Foster.	J. S. McArthur.
Oscar Guttman.	B. E. R. Newlands.
Douglas Herman.	Sir Robert Pullar.
David Howard.	Wm. Thorp, B.Sc.

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, B.

### Honorary Foreign Secretary:

Dr. Ludwig Mond, F.R.S.

**General Secretary:** Charles G. Cresswell.

**Offices:** Palace Chambers, 9, Bridge Street, Westminster, S.W.

### Editor:

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

## NOTICES.

### COLLECTIVE INDEX.

In reply to numerous inquiries, the compilation of the Collective Index is in active progress, part of the work being already in the printers' hands. The labour of revision and correction must, however, of necessity, take time; and it is hoped that those members who have already subscribed will extend their indulgence to the Indexer, who is making every effort to complete this vast work.

The prices are as follows:—

To Members (see Rules 25 and 27) and Past Members (see Rule 30): Libraries, Corporations, and Exchanges on the Society's List	Each copy 10s.
To Subscribers .....	12s. 6d.
To others.....	15s.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

#### LIST OF MEMBERS ELECTED 23rd FEBRUARY 1897.

- A. J. E. G., Health Officer, Ramsden Street, Huddersfield, Medical Officer of Health.
- Bacon, Wm., 4, New Court, Lincoln's Inn, W.C., Chemist.
- Bossett, Lewis L., 4013, Baring Street, Philadelphia, Pa., U.S.A., Analytical Chemist.
- Bower, Wm. H., 29th Street and Gray's Ferry Road, Philadelphia, Pa., U.S.A., Chemical Manufacturer.
- Brithwaite, Jno. O., The Rhydd, Hampton Road, Twickenham, Pharmaceutical Research Chemist.
- Brown, Wm., Salford Ironworks, Manchester; and (Journals) Brookland Terrace, Swinton, Engineer.
- Bush, J. M., 7, Hyde Park Street, W., Manufacturing Chemist.
- Button, Herbert, c/o Solvay Process Co., Syracuse, N.Y., U.S.A., Chemist.
- Chaffee, Albert J., Kern Mill Printworks, Whittle-le-Woods, Lancashire, Calico Printer.
- Davies, Saml. H., c/o H. S. Rowntree and Co., Cozon Works, York, Research Chemist.
- Elcix, Dr. Lorenz, 23, Arpley Street, Warrington, Technical Chemist.
- Garfield, Jos., 163, Penn Road, Wolverhampton, Civil Engineer.
- Graesser, Franz A., The Wrexham Lager Beer Co., Wapping Station, Liverpool, Manager.
- Hewitt, T. Lacey, Beechfield, St. John's, Higher Broughton, Manchester, Analytical Chemist.
- Holmeson, Matthew, 2, Leitrim Place, Wicklow, Ireland, Technical Chemist.
- Jacqué, Maurice, Fabrica de Dinamita, Galdacano, cerca Bilbao, Spain, Chemical Engineer.
- Kirkby, Wm., 14, Ducie Avenue, Oxford Road, Manchester, Chemist.
- Le Bosquet, Maurice, 328, East Eagle Street, East Boston, Mass., U.S.A., Technical Chemist.
- Macdonald, G. W., Fulwich Farm, Dartford, Kent, Explosives Chemist.
- McDox, Arnold, 184, Malpas Road, Brockley, S.E., Chemical Lecturer.
- Meslans, Prof. M., 12, Rue de la Grande Ile, Meaux (Seine et Marne), France, Professor of Chemistry.
- Millard, Edgar J., 40-42, Charlotte Street, London, E.C., Chemist and Manager.
- Morton, Jno., 50, North Road, St. Helens, Lancashire, Analytical Chemist.
- Mitch, D. Wilshin, Church Rd., Lostock Grahm, Cheshire, Chemist.
- Niemi, Michael, Kierkeby, N.B., Linoleum Manufacturer.
- Nicholson, Wm. J., 27, Dundonald Road, Kelvin-side, Glasgow, Chemist.
- Palmer, J. Howard, Apartado 48, Hermosillo, Sonora, Mexico, Assistant Manager, Gold and Silver Recovery Company.
- Poyser, Jos. C., Woodlands, The Priory, Higher Broughton, Manchester, Manufacturing Chemist.
- Quirk, Jno. S., Lead Smelting Works, St. Helens, Lancashire, Manager.
- Ridd, Jno., Garnockside, Glengarnock, Ayrshire, Metallurgical Chemist.
- Stein, Sigmund, 323, Vauxhall Road, Liverpool, Sugar Refinery Manager.

- Stones, Wm., Northwood, Seymour Grove, Old Trafford, Manchester, Chemist.
- Walker, Jas. W., Messrs. Alex. Walker and Co., Irvine, N.B., Chemical Manufacturer.
- Wielandt, Dr. Wm., Alleestrass, Gelsenkirchen, Westfalia, Germany, Chemist.
- Wilson, Ellwood, 101, Harrison Street, East Orange, N.J., U.S.A., Chemist.
- Zacharias, Dr. P. D., Philhellinon Street 22, Athens, Greece, Industrial Chemist.
- Zahorski, Dr. Boleslas, 22, Oxford Street, Liverpool, Technical Chemist.

#### CHANGES OF ADDRESS.

- Adrianse, J. S., 10 E. 34th Street; 321, Lexington Avenue, New York, U.S.A.
- Appleton, H. A., 1/o Leeds; 33, Upper Rushton Road, Thornbury, Bradford, Yorks.
- Barraclough, W. H., 1/o Chapeltown; Mortonley, near Sheffield.
- Boot, J. C., 1/o Brooklyn; American Sugar Refining Co., Jersey City, N.J., U.S.A.
- Brothers, Wm., 1/o Bury; Beechwood, Prestwich, near Manchester.
- Buchanan, Josh., 1/o Buffelsdoo; c/o New Transvaal Chemical Co., Ltd., Box 1829, Johannesburg, S.A.R.
- "Chemical News," 1/o Boy Court; 6 and 7, Creed Lane, Ludgate Hill, E.C.
- Cowburn, W. H., 1/o Asbley Road; Fernroyd, St. Margaret's Road, Bowdon.
- Dutton, W. H., 1/o Brockley; Southwood, Silverdale, Sydenham, S.E.
- Ede, H. E., 1/o Sheffield; c/o New Explosives Co., Ltd., Stowmarket, Suffolk.
- Gordon, J. G., 1/o Cannon Street; Queen Anne's Mansions, Westminster, S.W.
- Haller, H. Loft, 1/o Hull; 109, Tennyson Place, Bradford, Yorks.
- Hays, Jos. A., 1/o New York; 147, South 18th Street, Pittsburg, Pa., U.S.A.
- Hodges, H. B., 1/o Washington; Long Island R. R. Co., Long Island City, N.Y., U.S.A.
- Hunt, Bertram, 1/o Denver; 23, Stevenson Street, San Francisco, Cal., U.S.A.
- Hurry, E. H., 1/o New York; Bethlehem, Pa., U.S.A.
- Kawakita, M., 1/o Berlin; 14, Richmond Terrace, Clapham, S.W.
- King, J. Falconer, 1/o Russell Place; 43, Stirling Road, Edinburgh.
- Lee, T. H.; Journals to Hampden House, Phoenix Street, N.W.
- Lishman, G. P., 1/o Success; Buaker Hill, Fence Houses, Co. Durham.
- Lovejoy, F. W., 1/o Cambridgeport; 121, Lake Avenue, Rochester, N.Y., U.S.A.
- Lowe, Jas. S., 1/o Belle Rive Estate; Beauchamp Estate, Grand Rivière S.E., Mauritius.
- McCann, Owen, 1/o 62; 80, Stndley Road, Forest Gate, Essex.
- McGhie, J. Burns; Journals to c/o Quirk, Barton, and Co., Normandy Wharf, Rotherhithe, S.E.
- Maxwell, T., 1/o Braeside Avenue; 2, Wardlaw Avenue, Rutherglen, Glasgow.
- Ogata, S., 1/o Imperial Mint; Zohei Shikyoku, Okurasho, Tokio, Japan.
- Playfair, D. J., 1/o Woodside Terrace; Tramillau, Gowan, Glasgow.
- Quinn, J. C.; Journals to Rubber Tyre Manufacturing Co., Ltd., Aston Cross, Birmingham.
- Reid, Walter C., 1/o Tynemouth; 12, Wentworth Place, Newcastle-on-Tyne.

- Roseow, J. F., 10 Lowell; Norwich Bleachery, Norwich, Conn., U.S.A.  
 Rosell, Dr. C. A. O., 10 East 17th Street; 42, West 26th Street, New York City, U.S.A.  
 Schiller, L. J., 10 Boston; c/o Arbuckle Bros., 111, Front Street, New York, U.S.A.  
 Smith, Francis P., 10 New York; 77, Woodland Avenue, New Rochelle, N.Y., U.S.A.  
 Smith, Harry, 10 St. Thomas' Terrace; 30, Falconar Street, Newcastle-on-Tyne.  
 Sower, Alf.; Journals to Assay Office, Sylvester Street, Coolgardie, W. Australia.  
 Tinsley, J. D., 10 Virginia; College of Agriculture, Mesilla Park, N. Mexico, U.S.A.  
 Wetter, J., 10 Strand; 39, Essex Street, Strand, W.C.

#### MEMBERS OMITTED FROM LIST.

- Eastwood, Edw., Tunnel Soap Works, Wapping, E., Soap-maker.  
 Hills, Henry, Chemical Works, Deptford, S.E., Chemical Manufacturer.  
 Small, Evan W., Sunny Side, West Park, Newport, Mon., Director of Technical Instruction.  
 White, G., Ranton, Exeter, New Hampshire, U.S.A., Chemist.

#### Deaths.

- Demuth, Dr. L., Wharfedale, Edgbaston, Birmingham.  
 Fulton, Robt., jun.; accidentally killed at Ardeer Works, Stevenston, N.B.  
 Martyn, Wm., Afton House, Hebburn-on-Tyne. Feb. 12.  
 Tyler, Arthur J.; accidentally drowned at Marlburg, Germany.

Hon. Local Secretary:

John Heron, 110, Fenchurch Street, E.C.

#### SESSION 1896-97.

March 1st:—

- (1.) Mr. J. W. Lovibond. "Relation of Colour to Quality in Malt."
- (2.) Mr. J. H. B. Jenkins. "Helmer's Bromine Tests for Oils."
- (3.) Mr. J. H. Coste. "Note on the Analysis of Superphosphates."

N.B.—The Election of Officers and Five Members to the Local Committee will take place at the Meeting on April 5th. Nominations must be signed by Ten Members and sent to the Hon. Local Secretary not later than March 22nd. Members can only sign one Nomination. (See Bye Laws of Section.)

Meeting held on Monday, January 18th, 1897.

DR. R. MESSEL IN THE CHAIR.

#### ON THE BROMINE ABSORPTION OF FATS AND OILS, GRAVIMETRICALLY AND THERMOMETRICALLY.

BY OTTO HEHNER.

In the Journal of this Society for December 1896, p. 859, Dr. Lewkowitsch publishes a short paper on the gravi-

metric determination of the bromine value of fats, and therein attempts to disprove the accuracy of certain results and observations on this subject contained in papers by myself (Analyst, March 1896, p. 19), and by myself and Mitchell (Analyst, July 1895, p. 146).

On adding bromine to unsaturated fatty compounds, suitably diluted with a solvent like chloroform or carbon tetrachloride, the bromine immediately enters into additive combination with the fat, under more or less considerable evolution of heat. Little or no substitution of hydrogen, as a rule, takes place, at least not under the conditions laid down in the first of the two papers above referred to, in which it was sought to ascertain whether the weight of the bromo-addition compound formed stood in any definite relation to the iodine number as determined by Hübl's method, while in the second paper, by myself and C. A. Mitchell, relations are looked for, and conclusively shown to exist, between the iodine number and the heat evolved on bromination.

It was found that in a number of fats the percentage of bromine fixed by them was in molecular proportion to the Hübl number, for on calculating the bromine into its equivalent of iodine, figures closely approaching the Hübl numbers were obtained, as is seen from the following figures:—

Kind of Oil.	Hübl Number.	Bromine Addition multiplied by 1.587.
Olive oil .....	80.3	81.5
" .....	80.2	79.9
" .....	80.6	80.7
Lard .....	65.7	64.4
" .....	65.7	64.6
" .....	63.2	64.1
" .....	60.1	61.4
Maize oil .....	122.0	123.2
Butter-fat .....	31.0	31.3
Tallow-fatty acids .....	48.1	47.8

In the case of castor oil and of boiled linseed oil no close agreement could be observed. A sample of the former, with a Hübl number of 83.0 showed only 69.5 gravimetrically, and one of boiled linseed oil (Hübl 132.5) gave 159.5.

Dr. Lewkowitsch's numbers, as given on page 859 of the Journal do not agree with the above. I do not propose to examine them all in detail, but I will show, in the case of linseed oil, that Dr. Lewkowitsch is wrong.

Linseed oil has an iodine absorption of from 154 to 190, the great variation being largely due to modifications in the method of determination adopted by different workers. Unless the excess of iodine used is very large and the time of its action very prolonged, the iodine number is found too low.

Dr. Lewkowitsch finds two samples of linseed oil to combine with 18.68 and 10.4 per cent. of bromine, gravimetrically determined, corresponding to an iodine absorption of 29.65 and 16.5 respectively.

Now, by adding to linseed oil, or to the fatty acids obtained from linseed oil, dissolved in a suitable solvent, bromine in excess, a violent reaction ensues, with great evolution of heat. A little hydrobromic acid is formed, showing that some hydrogen of the fatty acid has been substituted, and at the same time an insoluble bromo-compound, found by analysis to be the hexabromo-compound of linolenic acid, separates. From the mother liquor of this large amounts of tetrabromo-linoleic acid can readily be obtained. I have, together with C. A. Mitchell, made many determinations of the insoluble hexabromo-compound obtained, and find that the weight of this alone invariably corresponds to more than the total bromine absorption found by Lewkowitsch, not to speak of the other bromo-compounds at the same time abundantly formed. Apart from this the strongest corroborative evidence exists, partly contained in a paper published by Rowland Williams (Analyst, December 1895, p. 277), who, as chemist to a very large firm of linoleum manufacturers, is in an excep-

he was glad to congratulate Mr. Hehner on the fact that he was one of the few chemists who did not come under the stricture of rushing into print with a trifling modification of the iodine method. Mr. Hehner's criticism of his paper was unfortunately mixed up with matter which was beyond its scope. For instance, he spoke about the heat test, whereas he (the speaker) had not said a word about it or anything else touched on in Mr. Hehner's further paper. Mr. Hehner had in his later paper made the positive statement that the action of bromine on unsaturated fatty substances is complete and quantitative. Against this statement he had put a series of figures, some of which agreed with Mr. Hehner's and some of which widely disagreed. He held that his figures contradicted in the most positive manner the usefulness of the gravimetric bromine process as a general process. Referring to his own experiments he admitted that in the case of fish and linseed oils they had been purposely pushed to the extreme in order to show that there was no knowing when to stop drying at 125° C. They had been carried out by three assistants who had had considerable experience in such work. With this method, however, they were helpless in the case of the last two oils and could not determine when the decrease ended. If it were desired to uphold this method as reliable, whilst his own experiments showed figures which did not agree with the author's, surely the only way out of the difficulty was a new series of experiments and figures. What he would have expected, would be a number of oleic acid figures agreeing with the Hübl method or some further notes as to how to work the method which seemed simple enough, but they had had nothing of the sort. He was not concerned to show why he agreed with Mr. Hehner in some cases. His case was that he totally disagreed in others. He could have gone further, but thought that he had done enough to show that the method was not a workable one.

Mr. C. A. MITCHELL said that it was difficult to find a reason for Dr. Lewkowitsch having obtained such good results with certain oils, whilst with others not even an approximate agreement had been obtained. One might have expected this in the case of linseed oil, which contained a large proportion of linolenic acid, but it was strange that the fatty acids from soap, which would certainly not contain much of the more unsaturated fatty acids should not have given more satisfactory figures. With regard to linseed oil, the long experience of Mr. Williams seemed very conclusive. Moreover, he (Mr. Mitchell) had recently made some determinations on linolenic acid prepared from linseed oil. By the Hübl process, this gave an iodine number of 241, as compared with 235.8 by the gravimetric process, and it was noteworthy in the case of the latter that the bromine compounds at the last began to gain in weight instead of losing. He considered that granting that Dr. Lewkowitsch's experiments were correct, his conclusions ought to have been stated in a more modified form, and that every chemist who examined all the evidence would come to the conclusion that the bromine absorption as determined in some cases by the gravimetric method and in others by the bromine heat value should go hand-in-hand with the Hübl method, though not attempting to displace it.

Mr. CASSAL deprecated any public discussion of the differences between two analysts of such high reputation as Mr. Hehner and Dr. Lewkowitsch. The results adduced by these two gentlemen were so widely different that experimental errors could not possibly be suggested as the cause. There was no doubt some fundamental difference in the method of working, and he felt sure that by private correspondence or discussion between themselves the true reason could be discovered and the matter dealt with satisfactorily. It was impossible that either of them could be so completely wrong as each seemed to suppose the other to be at the present moment. His own experience led him to the conclusion that Mr. Hehner's results correctly represented what took place on the application of the process, as he understood it.

Mr. HEHNER, in reply, said that he had no wish to add to arguments which had been brought before the meeting. Facts would speak for themselves. He had before the meeting, large samples of the bodies actually formed in the

experiments to which he had referred, and he felt sure that if Dr. Lewkowitsch would repeat his experiments he would find results which would agree with his own.

*Meeting held on Monday, February 1st, 1897.*

DR. R. MESSEL IN THE CHAIR.

## OZONE, ITS COMMERCIAL PRODUCTION AND APPLICATIONS.

By E. ANDRIOLI.

In a paper read before the Académie des Sciences, Fremy and Becquerel had confirmed Marignac and De la Rive in stating that ozone was oxygen condensed by electrification. Andrews, in a paper read before the Royal Society in 1856, held that ozone was simply an allotropic modification of oxygen. Soon afterwards Andrews and Tait published the results of researches on the density of ozone, and stated that only a minute percentage of oxygen could be converted into this substance, that electrolysis yielded less ozone than could be produced by electric machines, and that the sparks of an induction coil, even with the aid of two Leyden jars, gave only insignificant results. After Andrews came Brodie, whose paper on this subject will never be forgotten in the history of ozone. The physicists and chemists of that day used minute apparatus, which yielded a very small quantity of ozone. (The tube made by De la Rive had a diameter of one line.) On the work done by these instruments however, were laid down the rules and principles which guide us to-day in producing, no longer milligrammes, but kilogs. of ozone, in powerful generators.

In round figures, 1 kilo. of ozone is the theoretical quantity formed by the expenditure of one electrical horse-power-hour, but there is a wide slip between theory and practice. We have never yet obtained more than 50 grms. per electrical horse-power-hour, and we know of no apparatus which will give in continuous work 35 grms. per horse-power-hour. This, of course, refers to large ozone generators; and not to the small laboratory apparatus in which a high percentage of ozone is produced, and through which pure oxygen is sent after having been dried and brought down to a low temperature. The qualities of a good ozoniser are durability, easy construction, and efficiency. I will now give a brief sketch of what had already been done. The Siemens ozoniser consisted of a glass tube lined with a metal foil and inserted in a larger glass tube coated with metal on the outside. The ozone was formed in the annular space. About 10 years later, Ladd constructed an ozone generator which consisted of parallel sheets of glass covered with tin and alternately connected to the two poles of high electric tension generators. Numerous imitations of these two types have been and are still made, but without much success.

The most formidable obstacle to be surmounted in producing large quantities of ozone is the heat of the discharges which destroys ozone. When the temperature rises, the glass which separates the metallic electrodes loses its dielectric proportion and gradually becomes a conductor. Current soon passes through the glass, which cracks; and the apparatus ceases to work. It is all very well to produce ozone between glass surfaces, which being inoxidisable absorb no ozone, but the interposition of two dielectrics between two electrodes tends to reduce the yield of ozone, and it is really more advantageous to use a metallic electrode between dielectrics separating it from other metallic electrodes placed on either side. In this manner only and subject to certain conditions which I will enumerate can the minimum amount of heat and the maximum amount of ozone be obtained. I was the first to construct, five or six years ago, an ozoniser, where between two dielectrics and apart from them was a metallic plate. This new departure constitutes what I call the open ozoniser. The oxidation of the metallic plates by the ozone is after all very slight, and by special means can easily be prevented; and, if, by neglecting the prescriptions of servile practice, a yield of twice the amount usually produced is obtained, who would complain of the little harm which possibly is done by this oxidation?

Dr. Houzeau, so far back as 1871, held that the quantity of ozone resulting from the free passage of air between two naked metallic electrodes is greater than when the air passes round similar electrodes enclosed or sealed within glass, *i.e.*, when the air does not pass freely, and is in direct contact with the metallic electrodes. In the construction of a good ozoniser it is therefore quite unnecessary to electrify the air between glass surfaces, and to prevent it from coming in contact with any metal. It is not by modifying haphazard the shape and dimensions of an ozoniser that its power is increased; on the contrary, everything should be calculated and have a *raison d'être*. No revival of what has been done up to now and was not good 20 or 30 years ago can be so in 1897.

The greatest obstacle to overcome, I already told it, is the heat, which renders impossible the continuous generation of ozone. The electric silent discharge, notwithstanding its inoffensive appearance, causes a considerable rise of temperature, and it is easily conceivable that its luminous waves being continually emitted from the electrodes on to a glass surface will eventually yield disastrous results and reduce the yield of ozone to a minimum. To get over this difficulty the air to be ozonised must be left as little as possible in contact with the electrified surfaces, or with the points of the electrodes. The larger the electrodes the less satisfactory the ozonisation will be, because the longer the passage between electrodes coated, so to speak, with a layer of flame, the higher will be the temperature of the gas. This means that to work under the most advantageous circumstances, the distance to be traversed by the gas to be electrified must be extremely small. If this condition is not realised, and the ozonised gas is not very rapidly drawn from the electrifying surfaces, no quantity of ozone greater than 12 to 15 grms. per electric horse-power-hour will be available. If the air is driven through the ozoniser at a convenient velocity between the ozonising surfaces, and its contact with these surfaces is extremely short, a comparatively large amount of ozone will be obtained, even after abstracting from it the nitrous compounds, which increase as the contact of the air with the electrodes is prolonged.

My ozonisers give 30, 40, and 48 grms. of ozone at the utmost per horse-power-hour. Is not this very little? It seems to render its use prohibitive; but when Dr. Frölich of Messrs. Siemens and Halske, was taxed with not producing more than 20 grms., his reply was that 20 grms. produced by one horse-power-hour "will bleach 110 lb. of linen as well as grass bleaching during three days. It will in presence of chlorine bleach and refine 88 lb. of potato starch to such a degree that the colour becomes a clear white, and the bad odour and tastes are removed; if this is roasted and ozonisation continued, a product resembling gum arabic is obtained, 20 grms. of ozone being sufficient for 66 lb. of this product; the same quantity will ozonise a room containing 8,000 cubic metres in such a way that healthy persons can just endure it."

Do not suppose that we exaggerate the value of our work in speaking of our improvements in the construction of ozonisers. No progress, as a matter of fact, would have been realised if we had not had at our disposal powerful dynamos and high tension transformers, which the first workers on ozone never knew. There is nothing extraordinary to-day in loading a 5 or 6 Kilowatt alternator with several 10,000 volt transformers. It is only fair to acknowledge the services rendered by those electricians who have facilitated the development of ozone-making.

Speaking of alternators and transformers, these essential factors of ozone production, is it not very remarkable that the first alternate current dynamo combined with an induction coil (a real step-up transformer) was used by Dr. W. Spotti-wood in 1875, before transformers were invented, and that he used them for the production of ozone?

Listen to this extract from the "Philosophical Magazine" (1875, p. 380): "I have lately tried," says he, "a mode of exciting an induction coil which I have not seen elsewhere described, and which appears to promise valuable results. It consists in connecting the primary circuit directly with a dynamo giving alternate currents. I have

used one of M. de Meritens' excellent machines, driven by a 3½ horse-power Otto silent gas engine. The speed of dynamo so driven is 1,300 revolutions per minute. The advantages of the method are:—

"1. That, as the machine effects its own make and break, both the contact breaker and the condenser of the induction coil can be dispensed with.

"2. That the breaking of the primary, and consequently the delivery of the secondary currents is perfectly regular.

"3. That the quantity of the currents in the secondary is very great.

"With a 20-in. coil by Apps, I have obtained a spark about 7 ins. in length of the full thickness of an ordinary cedar pencil. But, for a spark of thickness, comparable at least with this, and of 2 ins. length, an ordinary 4-in. coil is sufficient."

Dr. Moncel was the first to demonstrate that very curious property of the induction spark of passing through glass without breaking it, and also producing ozone. This phenomenon, he said, is the consequence of the fact that under the influence of condensation the molecules of the insulating substance interposed are polarized like liquid molecules in electrolysis: so that they all contribute to condense the discharge from surface to surface on the sheet of glass. This electrification is complicated by momentary absorption of part of the charge, absorption which varies with the electrostatic capacity of the dielectric.

Books, 30 years ago, tell us that the electric effluvia is a luminous discharge, which spreads in an infinite number of small discharges over a large surface, and produces neither heating nor disintegrating mechanical action. This definition is excellent and very accurate except as regards heat. The electric effluvia or silent discharge is characterised by a dissemination of sparks, feeble light, and small amount of heat produced. But when it acts on a gas between two electrodes, there is a strong evolution of heat, which hinders and finally stops the production of ozone. The difference between the silent and the disruptive discharge is that the latter is longer in duration and causes heating in the gaseous matter through which it passes, thus preventing formation of condensed products. The silent discharge on the contrary, which is, as a great chemist remarked, only the diffusion of the ordinary spark in thousands of discharges which occur from molecule to molecule in the electrified gas, crosses a much smaller interval. The duration of each isolated discharge is much shorter than that of the spark, and the matter acted on is less, so that condensed products are formed and are withdrawn by reason of the extreme brevity of the discharge from any destructive effect. It is the silent discharge and not the disruptive discharge which is utilised for the production of electrostatic ozone.

When the current from a high tension transformer passes between two parallel metallic plates, apart one from the other, there is an explosion, a violent discharge with evolution of nitrous emanations, but there is hardly any ozone produced unless the plates are at such a distance that owing to the resistance opposed by the dielectric properties of the ambient air, no disruptive discharge is possible. For reasons which it would be too long to explain, it is not desirable to try to produce ozone by reducing long sparks and making them smaller and smaller until they resemble the silent discharge. The dielectric properties of the air are variable, and I have preferably adopted the old and simple contrivance of a dielectric, such as glass or porcelain, which, after all, answers very well my purpose.

A short description of this apparatus will enable you to judge if I have constructed an ozoniser which can work in a continuous manner and produce ozone on a comparatively large scale. My main object has been to have a large electrifying surface, and at the same time to prevent the rise of temperature caused by the electric effluvia. My electrodes are boxes through which cold air or a cooling liquid may circulate. One set of electrodes is connected to one pole of a high tension transformer, the other is connected to the other pole, and there is between each electrode a glass separator or dielectric. The electrodes are narrow and long; they are kept at a proper temperature by cold air or water; they work on both sides, and their point-

bearing surface is very large and active. But it is not sufficient to have some means for cooling them, the longer the air is in contact with the electrodes and with the dielectric, the warmer it is, and therefore the smaller the quantity of ozone formed. To obviate this, the air is forced from beneath between the electrodes, through the slits or apertures of a false bottom. Its velocity is high; the gas traverses a very short electrifying space, and almost as soon as the gas is ozonised it is removed from contact with the glow of the silent discharge.

Although the oxidation of metallic electrodes is not so dangerous as some people say, and the loss of ozone in this respect is therefore slight, we none the less studied how to remove or at least diminish considerably the possibility of this occurrence. This we attained by covering our electrodes, that is to say, our point-bearing metal boxes, with a few coatings of a varnish, which resists a much higher temperature than that which might rise in ordinary ozonisers, and which is practically inoxidisable.

I can employ flat electrodes, but I prefer electrodes provided with numerous points, which on both sides of a dielectric separator, I set to work points against points, or points against flat surfaces. There is more to be said than one would think about the influence and rôle of points in the production of ozone. It is obvious that the electric effluvia will flow out better and more powerfully from a multitude of points than from a flat plate, on which the tension is uniform. More ozone is formed on angles or points than in condensers with flat surfaces, or in plain tubes, &c. It is at the top of a cone that electric density has its greatest value; and electricity accumulates there so abundantly when the point is very sharp, that, in spite of its insulating properties, the ambient air is electrified, repelled, and replaced by a fresh amount of air, which, in its turn, electrified, and so on. Points have not, as Franklin thought, power to attract the electric fluid, but they have the property of liberating and discharging with the greatest rapidity the electricity with which they are charged. Each square foot of my electrodes bears 46 rows of 56 double points, and in my ozonisers of 12 boxes the number of points is 53,760.

While studying the question of commercial ozonisers I pursued the construction of small apparatus for household employment, and since 1891 I had made various models of ozonisers, which worked in a satisfactory manner, all of which were what I call open ozonisers, *i.e.* where the air circulates freely and is partially transformed into ozone. But in 1893, having noticed the feeble luminosity of an incandescent lamp when placed in contact with only one of the terminals of the secondary circuit of an induction coil, it struck me that I could use a vacuum glass tube, traversed by a central wire, and surrounded by a spiral made of serrated wire. I put the central wire of the tube in contact with one of the terminals of an induction coil, and the outer spiral with the other. At once the tube filled with a beautiful whitish brightness, and simultaneously the violet glow of the silent discharge formed ozone in abundance between the surface of the glass tube and the points of the spiral. No glow, no ozone! no vacuum in the tube, no luminosity! and if the points of the aluminium discs which I substituted round the vacuum tube for the tinned steel spirals are too near the glass, the amount of ozone will be much less than when a space of about a millimetre separates the glass from the points. This last remark is applicable both to small and large ozone generators.

Eminent physicians, well known in England and abroad, have prescribed ozone in many cases. Ozonised oxygen insufflated on wounds produces a remarkably beneficial action. I am informed that an ulcerous wound, which had resisted every other treatment during two years, began to heal at once, and the wound is now filling with healthy tissues. In rooms, it purifies the air. Many consumptive people have been cured by inhalation of ozonised oxygen. The essential point is not to administer ozone *in extremis*. If you wish to see some examples of the efficacy of these ozone inhalers, I may refer you to the *Lancet* of 9th May 1896, and the *British Medical Journal* of the 10th October 1897, where two doctors tell how they treated patients, with complete success, in cases of anæmia and

other diseases, simply by employment of the ozone of the luminous tubes.

When an ozoniser gets hot, it is not sufficient to stop it for a few moments to allow it to cool, in order to prevent the destruction of ozone. Hantefeuille and Chappuis have found that once started, the destruction of ozone continues. The only way is to wait until the electrodes are quite cool. It is to the unknown temperature of the electric effluvia that the instantaneous decomposition of ozone must be attributed, and if to this unknown temperature we add that of the exothermic decomposition of ozone back into oxygen, it is easy to realise the importance of designing ozone generators, which will not heat, or will not heat much.

It results from Clerk Maxwell's researches on the manner in which temperatures are distributed among gaseous molecules that ozonised oxygen, even at ordinary temperatures, returns to the state of oxygen, because there are always some molecules which are at a higher temperature than others, and these determine the commencement of dissociation. The lower the temperature, the greater the probability that ozone will not be destroyed. In the end, more ozone is produced than at ordinary temperatures; at medium temperatures ozone is decomposed, and at 250° C. its existence is impossible; but what we are in ignorance of, although we might know the temperature of the gaseous mass in an ozoniser, is the temperature to which oxygen is raised by electrification when it is allotropically transformed.

The methods of titration of ozone are the same to-day as 30 years ago, and nowhere in any treatise of analytical chemistry will you be able to find a mode of quantitative determination of the ozone commercially produced by the electrification of atmospheric air. The only method I know is the one adopted by Marié Davy at the Montsouris Observatory for titrating the ozone of the atmospheric air, and I have been told that it is not absolutely reliable. Quite recently I invited a specialist, one of the men whose experiments on ozone are the best known in the scientific world, to come to London to make, by his own method, a quantitative determination of the ozone produced by my apparatus. But when he was informed that he would have to determine the ozone contained in electrified atmospheric air, he wrote that his method was devised for ozone produced from pure oxygen, but he could not use it for atmospheric air because of the nitrous compounds present.

Few persons at the present day can imagine what an important part nitrogen and its compounds have played in the history of ozone, and we may smile at the dogmatic and contradictory assertions, which, less than 50 years ago, chemists hurled at each other. After having spoken of ozone as a new substance, Schonbein found nitrous acid in it. Sterry Hunt considered there were nitrites of ammonia present. Rivière and De Fallenberg declared that the ozone of Schonbein was simply nitrous acid. In 1862 Sauvage asserted that ozone does not exist, and that what was called ozone is merely an oxygenated nitrogen compound, or rather the aggregate of all the oxygenated compounds of nitrogen. Under electric action, he said, the oxygen is charged with positive electricity and electrifies the nitrogen with which it is in contact; the two gases combine and form a nitrous substance which has been called ozone.

Williamson stated that electrolysis gives peroxide of hydrogen and not ozone, that the electric spark only forms nitrous acid; according to another, electric discharges in a mixture of oxygen and nitrogen produce hyponitric acid. Dubrunfaut denied the hypothesis of the existence of an allotropic oxygen, and his theory was that ozone is only a nitrous compound. It is quite beyond doubt that when atmospheric air is subjected to electric effluvia, nitrous products are formed; but with our small vacuum tube, which contains an electrode, and is provided with an outside armature where the glow of the silent discharge appears, and ozone is generated, there are little or no nitrous products, because the tension is too weak and the air is too rapidly renewed to allow of their formation. Ozone forms in the air, and even somewhat rapidly, with comparatively low tensions, whereas Berthelot remarked, the proportion of nitrous products becomes nil, or, more accurately, unappreciable by the existing methods of research. The

formation of ozone and that of nitrous compounds are not correlative; and therefore to obtain a maximum quantity of ozone and a minimum of nitrous products in the electrification of atmospheric air, the gas must pass with the greatest possible velocity in an apparatus where the electrifying surfaces are long but not high.

If low electric tension were sufficient to form a large amount of ozone, said Berthelot, the oxygen of the atmosphere on which low electric tension constantly acts, would soon destroy all the organic and other oxidable substances spread over the surface of the earth. Does this not remarkably compare with this statement of an illustrious English chemist who, speaking of the combustibility of nitrogen, said, "the reason why, when once nitrogen is set on fire, the flame does not spread throughout the whole atmosphere, and deluge the whole world in a sea of nitric acid is that the igniting point of nitrogen is higher than the temperature produced by its combustion, and therefore the flame is not hot enough to set fire to the adjacent gas."

It requires only a very slight contact of the air with the glow of the silent discharge to produce ozone. The formation of ozone is instantaneous. Nitrous products take longer to form than ozone; the less the air is heated by the silent discharge the less nitrous compounds there will be without any decrease in the amount of ozone.

Ozone may be regarded as an explosive since it cannot safely bear a pressure of more than 7 to 9 atmospheres, and then is assumed to be decomposed and to explode. According to Jonglet, nitro-glycerine, dynamite, nitrogen iodide, or chloride, and similar substances explode in contact with ozone and the properties of common powder which has been in contact with ozone are impaired after six weeks.

Jean, a French chemist, who was one of the first to devise an ozoniser, observed that when carbonic acid was passed between the glass plates of his condenser it was decomposed into carbonic monoxide and oxygen, which latter was partly converted into ozone. Sir Benjamin Brodie also was struck by the fact that in electrifying oxygen by the silent discharge, he only converted 20 per cent. of it into ozone. His description of the very little known experiments he made, is worth quoting:—"It occurred to me as possible to replace 80 per cent. of oxygen, unaffected by the action of electricity, by an indifferent gas, and thus to effect the complete conversion of oxygen into ozone."

This idea was the starting point of the following investigation:—

When pure and dry carbonic acid gas is subjected in the induction tube to the electric action, a certain proportion of the gas is decomposed into carbonic oxide and oxygen a portion of which appears in the form of ozone. Various experiments were instituted with a view of ascertaining the conditions most favourable to the conversion of a large proportion of this oxygen into ozone. The conclusion at which I arrived was that the greatest proportion of ozone in relation to the total oxygen was produced when a rapid current of dry carbonic acid gas was acted upon at low temperature. When those conditions were realised, it was found that 75 per cent. of the total oxygen eliminated in the induction tube by the decomposition of the carbonic acid gas could readily be converted into ozone, but that it was difficult to pass this limit."

(Proceedings, Royal Society XXI., 1872, pp. 483, 84, 85.)

Thus, so far back as 1872, Sir Benjamin Brodie recommended a rapid passage of the gas through the ozoniser to obtain high results, and it is because this was not, or could not be carried out, that most ozonisers could not and cannot be turned to industrial account.

Another remarkable fact in connection with the electrification of carbonic acid, is that according to Berthelot it leads us to suspect the existence of percarbonic acid. The substance formed attacks oxidisable bodies with great violence.

In regard to the employment of ozone to the manufacture of aerated waters, there are two points to be considered—the absorption of ozone by the water, and the formation of carbon monoxide by the silent discharge. The latter may not be found to be so noxious as would be surmised. Gruber has stated that below a certain point of dilution,

say, 0.02 or 0.05, this gas ceases to be dangerous, and it appears that below this limit, carbon monoxide, when it finds its way into the human body, converts carboxy-haemoglobin into oxyhaemoglobin. On the other hand, Prof. Olezewski, in a letter dated 1896, said, that because of the low solubility of oxide of carbon in water, it is probable that the solution would be harmless, and he added that ozonised carbonic acid could be used safely if when leaving the ozonisers it was forced through a chromic acid solution, which would convert the oxide of carbon formed into carbonic acid. The real difficulty is that ozone does not readily dissolve in water, and that in contact with the metal of the cylinder through which it is forced, it decomposes. The sole result in this case is that there is a little more oxygen in the water than there was before.

The only industrial applications of ozone at the present day, which gives results, that is to say, real profits, and I may add, substantial profits, is the manufacture of certain artificial perfumes.

What importance should we give to the ozonisation of beer casks to cleanse and purify them, that is to say, destroy the moulds, micro-organisms, &c.? In breweries, it appears, they have excellent methods of destroying ferments, which cause diseases of beer? I merely mention this, because of the sterilisation which ozone effects very rapidly.

Very few people know that ozone can be utilised for making "dégras," i.e., spent oil, which is an indispensable substance in the leather industry. Oxidised fish-oil, mixed or not with animal oils, gives an artificial "article," which is cheaper than genuine "dégras" and possesses all its properties. For "dégras" as for most other applications of ozone, it is not enough to force ozone into the substance to be oxidised, there are conditions to be fulfilled which the manufacturers only know and there is a limit to oxidation which must not be overstepped.

It is preferable to ozonise wood for making musical instruments, instead of drying it by the traditional method, which consists in keeping it for a long time in sheds. The sounding-boards of pianos have then a great sonority, and resist variations of temperature better, which is important for exportation. Woods for cabinet and carriage making when seasoned by ozone have a more pleasing appearance; their tint is softer, and they take varnish much better.

There are in Germany two factories where Messrs. Siemens and Halske two or three years ago have introduced ozone. In one of them they bleach linen cloth and yarns, and in the other starch and other amylaceous products are bleached and refined. In Greifenberg (Silesia), fabrics and yarns are bleached; the starch works are at Kyritz, but ozone is not employed singly. Decolorisation by ozone alone is a myth: Messrs. Siemens, by alternate passages through hypochlorite of calcium and ozone, bleach well and cheaply. It is what we may call chlorozone bleaching, had not this term been already adopted.

We also wished to subject to an ozone treatment the starch manufactured in this country; but when we applied to manufacturers, they told us that they only make rice starch, which is white, and that bleaching is not required. I will add that the ozonised products of Messrs. Siemens are quoted much higher than ordinary starch, leigum, and dextrin. In vinegar works there ought to be a great advantage in adopting the ozonisation of the wash.

We made numerous attempts to decolorise molasses, syrups, and moist sugar, but they were not crowned with any brilliant success. Firstly, the action is slow, and consequently the bleaching, which is never very marked, is expensive.

In the case of drying oils, it is very desirable to render them paler and transparent for the manufacture of varnish and for their other uses. There is no need to alter the plant for oil-drying or linoleum works, or for any other oil or fat works where oxidation has to be replaced by ozonisation. Wherever there are installations for forcing or aspirating air through fatty masses, you have simply to run this air through one or several ozone generators, whence in an ozonised condition it may pass into your receivers, where it does more work than blown air.

In Schoabin's time "ozonised turpentine" was the name given to oil of turpentine strongly agitated in the air and light, and which in this state possessed decolorising and strong oxidising properties. He was the first to form peroxide of hydrogen by agitating with air turpentine and water. I have no intention of discussing the existence or the absence of ozone in aerated turpentine. It is not air, but ozone, or rather ozonised air, which I pass through turpentine, either singly or mixed with water. I obtain, then, really ozonised turpentine and the water with which it has been bubbling is, according to the duration of the contact, a more or less rich solution of peroxide of hydrogen. Thus, by the aid of ozone, we can make peroxide of hydrogen, but you can pass as much ozone as you wish through water there will be no trace of peroxide of hydrogen in it. I will add that I look with the greatest confidence on ozone as a cheap producer of peroxide of hydrogen. This ozonisation of turpentine and water is much more rapid and energetic than mere oxidation by air, and if the products of this ozonisation were combined with coadjutant chemicals, no doubt a sanitary compound would be obtained of exceptional value. The disinfection of rags by ozone is a topic which must not be neglected.

Ozone has shown its value as a bactericide and germicide. An installation is being constructed at present near Paris for sterilising water from the Seine, by means of the Tindal and Van der Sleen apparatus. The Municipal Council of Paris has granted a concession for the daily disinfection during three months of a certain quantity of water—a concession which will be made permanent if conditions of efficiency and economy are realised. It is estimated that the sterilisation of 5,000 litres of Seine water requires one electric horse-power-hour. The practicability of the sterilisation of water depends on the quantity of ozone available per horse-power-hour. With only 10 or 12 grms. of ozone it is evident that there is little chance to economically purify contaminated water. But here we have the starting point, which is the deadly action of ozone on bacilli and even spores.

As a bleaching agent ozone will not do the work which hydrogen peroxide or bleaching powder does. When alone it will not bleach tissues nor fibres. It only appears to bleach when in conjunction with other bleaching agents.

There is a note by a certain Wiedemann read before the Académie des Sciences, in which he stated that he had erected in Boston works in which he treated daily 300 barrels of raw whisky, the resinous matters of which which disappeared in 20 minutes under the mellowing action of ozone. It is evident that the improvement of alcoholic liquids being due to oxygen, the ozone treatment must hasten this effect. Ozonised air must not be used, however small the percentage of nitrogen compounds present, it would be detrimental to the quality of the final product. Electrified oxygen only is beneficial. It is difficult to say which is the best practical way to adopt for the treatment of alcoholic liquids. It is indispensable to take into account the nature of the wines to be treated and not to ozonise light wines in the same manner as richer varieties, sweet wines like dry, and so on. Port wine is that which shows the effect of ozonising most rapidly. At the end of two or three days a deposit is formed, and goes on increasing until a very clear wine is obtained, which has an appearance it would only have after remaining in bottle for years. The difficulty is not to overdo the treatment.

It is amusing to review the post of ingenious combinations which have been contrived in order to sell under the name of ozone, medicaments, beverages, disinfectants, and panaceas, in which ozone plays a very small part, or none whatever. If people understood how little ozone is retained by water and liquids, there would be fewer persons attracted by the grand alluring name of ozone spread out on labels. Pseudo-ozone seems to be more in demand and pay better than genuine ozone.

The production of an ozone generator constructed on a rational basis, such as was suggested by scientists like Sir Benjamin Brodie, and which would answer the purposes of manufacturers desirous of applying it on a large scale, has been my chief aim. The great problem is the economic production. I do not pretend to have solved it, but I think

that I have constructed a good strong commercial apparatus, which can be adapted to the needs of manufacturers. Its average output is, as I said before, more than 30 grms. of ozone per horse-power-hour. Although this is very little, it is something, and I am sure much higher results are possible.

Calculating at the rate of 30 grms. per horse-power-hour, the cost of ozone would, at 1d. per horse-power-hour—

	£	s.	d.
300 grms. for 10 horse-power-hours	0	0	10
3 kilogs. for 100 " "	0	8	4
30 " " 1,000 " "	4	3	6

I hope to be able to tell you ere long in a more complete paper, the progress which we realised, what we have done in various works, and I will give you facts and figures about the advantages arrived at by replacing air by ozone in several large branches of industry.

#### DISCUSSION.

Mr. A. GORDON SALAMON said that he had had some experience of the industrial working of the apparatus explained in the paper just read. That paper contained more information on the subject of ozone than was available in any other source, and he hoped the author would render it still more complete and valuable by adding to it a short appendix of the bibliography of the subject. He had been concerned in one of the first important industrial applications of ozone, and he was justified in saying that the results had been successful, both practically and economically. He would warn industrial chemists, however, not to indulge too much in theoretical speculations on the subject, or they would probably be disappointed. It was far better, in this case, to rely on the actual product as obtained than upon costs based upon theoretical yields. It must be recollected, too, that the stated production of the apparatus per horse-power-hour must, in the first place, be divided by three, because only one-third of the ozone produced was, in nearly all cases, actually available for oxidising purposes. Next, they must take into consideration the velocity of the air passing through the machine, as the production and any comparisons must obviously largely depend on that. With regard to any ozone machine, the great drawback was the tendency to heating, to which the author had called attention. Unless this could be satisfactorily obviated, he did not think the apparatus would be likely to succeed in industrial applications. Whether the author's means to that end were the best, time alone would show; at any rate, he had rendered service in pointing out that the heating of the ozone, and its consequent decomposition, was the important point to be avoided. Whether that heating could best be reduced to a minimum by a system of point discharge, was a question upon which he felt some doubt. He was satisfied, however, that the author had hit the true point in ozone production when he stated that the greater the frequency the better the yield and the less the heat produced. With regard to the source of production, he thought that at present, except in special cases, they were limited to atmospheric air. One could not at present deal with the industrial application of ozonised oxygen. To do so would be to court failure from many points of view—mainly because of the expense involved; and next, because of the heat developed. With respect to the industrial application of the apparatus, there were difficulties which the author had not touched upon, but which would become apparent to anyone dealing practically with the subject. For instance, he regarded the fittings of the apparatus as constituting just as important a feature as the apparatus itself. He had experienced much trouble, disappointment, and indeed loss in the rotting of the various pipes and fittings employed in the ozone apparatus. It was only right to mention this, and he was sure that Mr. Andreoli would admit its importance. The question of moisture also constituted an important difficulty, especially when using ordinary air as the source of production, seeing that to deal with dry air was practically impossible. He knew that it was possible to overcome these difficulties; at the same time it was only right that they should be pointed out to those who might be desirous of experimenting with the machine. As to the future of ozone, he would not like

to say much, except that from what he had already seen achieved, he believed it had a great future. Where one had, under ordinary circumstances, to employ large volumes of acid or other oxidising material in order ultimately to obtain a mere kernel as the oxidised product—anyone acquainted with the cost of manipulating large bodies of material would admit the industrial economy of employing a good ozone apparatus and good means of distributing its products. Again, ozone might have further applications, such as the acidification of alcohol, the sterilisation of water, the thickening of oils, for which purposes the ordinary oxidising agents were comparatively useless. He had seen Mr. Andreoli's machine applied to such purposes, and, so far as he was in a position to form an opinion, he regarded its future as most hopeful.

Dr. W. S. SQUIRE asked whether the author had tried the effect of passing air, artificially cooled to a very low temperature, through the apparatus. That would, he thought, get rid of the difficulty caused by the heating of the air when used at the ordinary temperature. D'Arsonval had produced ozone by passing the electric discharge over liquid oxygen in a suitable apparatus, and he believed with fairly good results. If oxygen could be converted into ozone in larger quantities in consequence of using a very low temperature, it might be worth while even to employ liquid oxygen, for one would in that way get rid of the difficulty arising from moisture, because the gaseous oxygen derived from liquid oxygen was absolutely dry. As to the possible industrial applications of ozone, he feared they would be extremely limited. Mr. Salamon had suggested that it might be used for the acidification of alcohol. It appears that the utmost quantity of ozone that could at present be obtained was 48 grms. per horse-power. Of these, only 16 were really available for oxidising purposes. Now 16 grms. of oxygen—that is to say, one horse-power-hour—were required to convert 23 grms. of alcohol into 30 grms. of glacial acetic acid, a body worth at the present time about one shilling per kilogramme. These figures showed how utterly hopeless it was to use ozone for the purpose suggested. Ozone might perhaps be used to destroy certain colouring matters, for it frequently happened that these bodies, although affecting the tint of large quantities of material, were themselves present only in very minute proportions.

Col. ENGLEDEW thought that the difficulty arising from overheating in the production of ozone had been considerably overrated. He was now using a generator that could be run for six hours continuously without perceptible increase of temperature. The heat might rise after eight hours, when a new generator would take its place until the first had cooled down. They had thus no difficulty in continuously working. It was difficult to explain the precise cost of production, as they had not yet been able to measure it; but after two months' experimental working he might say that the cost for electrical energy did not exceed 12s. He felt sure that at that rate ozone could be adapted to commercial purposes. They had tried it for the deodorisation of sewage. A large beaker of very evil-smelling sewage was rendered quite inodorous in two minutes. They had also experimented with oils, and these had been perfectly sterilised. He need hardly remind members of the beneficial effects following the use of ozone in surgical cases, the prolongation of the life of the late Sir John Millar, being a notable instance of its value in that direction. There could be no question, he thought, that ozone would come into general use for the ventilation of hospitals, factories, &c. Mr. Andreoli's work was the best existing paper on the subject of ozone, and the best thanks of those interested in the subject were therefore due to him for his valuable researches in it.

Mr. OTTO HEHNER agreed with Mr. Salamon and other speakers as to the immense amount of suggestions contained in the paper. Some of these might yield useful results in the future; at the same time there was much that was purely speculative in character. He would have liked to have seen something more tangible than a catalogue of possible applications of ozone, and to discuss these applications of it from the point of view of pounds, shillings, and pence. He feared there was nothing in the paper which would induce a manufacturer to spend a single

farthing on plant for the production of ozone. He would like to know precisely what the author meant by a production of 48 grms. Did he mean 48 grms. of ozone or of active oxygen? In the former case only one-third of that quantity, namely 16 grms., would be active and available, and such a production per horse-power-hour was hardly satisfactory. It might, as Dr. Squire had said, be useful in dealing with certain colouring matters, and in bleaching generally there was a strong probability that ozone would be useful in future. But to talk of sewage purification by ozone was somewhat ridiculous, and likely to do harm to the commercial future of ozone.

Mr. SALAMON asked if Mr. Hehner would state the amount of oxygen required to deodorise sewage.

Mr. HEHNER, continuing, said, no doubt Mr. Salamon knew that as well as himself; but deodorisation was not the only question. There was, further, the removal of the organic matter, thus rendering sewage incapable of again becoming putrid. There were statements of fact in the paper which were open to doubt. If it were true that carbon monoxide could be produced from carbon dioxide by ozone, it was an interesting observation. In the last number of the *Berichte* had appeared an article discussing the action of ozone upon moist carbon monoxide, and showing that this was transformed into formic acid. The reduction of carbon dioxide mentioned in the paper was contrary to what one would expect. He did not say that ozone had not a future before it, but before it could be applied commercially a great deal remained to be done.

Dr. L. T. THORNE had had an opportunity of trying Mr. Andreoli's apparatus, and had also for many years past taken a deep interest in the question of ozone production. He could cordially agree with Mr. Salamon's remark that this question should be approached with an open mind, for the text-books were extremely unreliable. Mr. Hehner had referred to the uselessness of attempting to treat sewage by the small quantities of ozone now available. The force of that argument was obvious, and indeed Mr. Andreoli had disclaimed any such application of it on the basis of present production. On the other hand, they must be careful not to go to the opposite extreme, and imagine that ozone was not available for many other purposes, for in most cases they were hardly yet aware how much ozone was required for the work to be done. Mr. Hehner and Mr. Salamon had come into conflict over the sewage question; personally, he was inclined to side with Mr. Hehner, but would not like to be as positive as the latter was, or to say that ozone might not eventually be used in conjunction with other sewage purification processes. Mr. Hehner had spoken of one-third only of the ozone produced being available for work, but from his own experience he (the speaker) was not so sure of that being so in all cases. If one simply oxidised  $\text{SO}_2$  into  $\text{SO}_3$ , one could only utilise a third of the oxygen in the form of ozone; but he had found in the case of mixtures of oxygen and chlorine, that in some cases (such as in the bleaching of some natural colouring matters) the whole of the oxygen was made available for oxidising purposes by the presence of the nascent oxygen liberated by the chlorine; and certain experiments seemed to point to similar effects from the active oxygen atom in the ozone molecule. That would make a vast difference to the industrial application of ozone. From his own experience of the apparatus he could confirm Mr. Andreoli's figures, and in the quantitative determinations he had used what he considered the most accurate method, namely, passing the ozonised air through acidified potassium iodide and measuring the iodine liberated. In that process they got the interference of the nitrogen compounds, and with the view of eliminating these, he had passed the ozone first over a solution of caustic potash or over pumice stone soaked in it. To his astonishment, the ozone was reduced to a much greater extent than he had expected. In one case the amount was over 50 grms. before washing, and was reduced to 28 grms. after. In order to verify the results he had modified the method by determining the apparent ozone; and under the same conditions had determined the nitrogen oxides by absorption in potash and subsequent estimation as ammonia. He then found that the quantity of ozone to be subtracted from the first determination was not 45 per

cent., but under 8 per cent. only; and, further, that in ozone produced in the Andreoli apparatus, the proportion of nitric oxide was very small. He had also found that ozone was a much less stable compound than was generally supposed, and was even partially decomposed by contact with aqueous potash. The instability of ozone was confirmed by Mr. Shenstone in his recent interesting paper. The question of moisture was of great importance in relation to the industrial application of ozone. Mr. Salamon had laid much stress on that point, though their information as to the extent to which moisture prevented ozone production were not very definite. In practice, only moderate dryness of the air seemed necessary.

Mr. SALAMON remarked that he had not spoken so much as to the influence of moisture as affecting the yield of ozone, but rather of its action.

Dr. THORNE, resuming, was glad to have that point cleared up, because he thought that the need for dryness in the air had been over-estimated. That point was emphasised by Mr. Shenstone, who had found that in using absolutely dry oxygen he got practically no ozone at all, because of the rapid decomposition of absolutely dry ozone. With regard to Mr. Hehner's remarks as to the production of CO from CO<sub>2</sub> by ozone, he thought there must be some misunderstanding. He believed that if a mixture of carbonic acid and oxygen were subjected to the electric discharge, some of the acid would be reduced to carbonic oxide, but certainly ozone itself did not convert carbonic acid into carbonic oxide.

Mr. W. F. REID regarded the paper as divisible into two parts—practical and speculative, the former being much outweighed by the latter. However interesting the apparatus before them, and the possible future applications of the ozone produced, he agreed with previous speakers that at present the industrial use of the process was very limited. He understood the author that even the claim that it might be used for bleaching was mythical. Then, again, various authorities differed as to its action upon alcoholic liquors. Further, the author had stated that ozone was not absorbable by water. In regard to one suggested application, namely, the forcing of ozonised air through oils, they had in atmospheric oxygen everything that was wanted; and if they employed a too active form of oxygen they might get a further stage of oxidation which would be injurious. Thus every suggested large field for the industrial application of ozone seemed to be cut off. He would like to ask, as to the current of air passing through the apparatus, whether the gain in the yield of ozone was not more than compensated for by the dilution of the current. It occurred to him that the oxides of nitrogen which seemed to be always produced at the same time as ozone might possibly at some future time themselves become a source for the chemical production of ozone.

Mr. LING understood that an eminent scientific man had refused to estimate a sample of Mr. Andreoli's ozone on account of the presence of oxides of nitrogen. It seemed to him that most of the applications of the product proposed by the author would be vitiated for the same reason.

Mr. BERTRAM BLOUNT regarded the paper as made up of extremely suggestive matter, but hardly useful from a practical point of view, and it seemed to him that discussion on a subject so highly speculative in its character was out of place in that Society. The results obtained by authorities such as Shenstone, to the effect that ozone can be obtained in quantity under particular conditions, had been to a great extent ignored. Further, he thought that chemical engineers would resent the implication that they were unable to cool and dry a gas economically; and the suggestion that because of this so-called difficulty, pure oxygen could not be used, he regarded as preposterous. For his own part he disbelieved in products which defied analysis, and as it had been suggested that the estimation of ozone was beyond the power of ordinary methods, he would like to know the method adopted to that end by Mr. Andreoli. Dr. Thorne had stated that in some cases there was reason to suppose that the whole of the oxygen in ozone was utilisable. That statement was interesting and important, and, if it was a fact, indicated a great advance towards the industrial

application of this body. He was, however, anxious to learn the evidence on which Dr. Thorne had based his statement.

Dr. S. RIMEY believed that there was a great field open to ozone in the future, but further experiments were required. He thought that Mr. Salamon had put the whole matter in a nutshell, and with his remarks he cordially agreed, excepting his sanguine opinion as to the applicability of ozone to vinegar-making. He thought it had a future as a disinfectant and germicide; but, apart from the reasons adduced by Dr. Squire with respect to its use in treating alcohol, it seemed to him that its application in that way was further prohibited by the fact that it would kill the specific organism whose action was necessary to the conversion of alcohol to acetic acid. With regard to the question of the solubility of ozone in water, some years ago a Mr. Fahrig had sent him a solution of ozone in salt water. The fact that it was soluble in the one liquid and not in the other possibly afforded an explanation of the action of electrolysed hypochlorites to which reference had been made. It would probably be too expensive to oxidise the whole of the organic matter in sewage, and he did not know that it was necessary. What they had to do was to destroy the pathogenic organisms in sewage, and it seemed to him quite possible to use ozone for that purpose after a cheaper oxidising agent had done its work. He was at present studying its behaviour on drying and other oils, and hoped to obtain useful results in that direction.

Mr. O. GUTTMANN observed that among the many uses of ozone contemplated by Mr. Andreoli, he had not included its use for the bleaching of beeswax and bones. Both of these were important industries to which he thought it might be applied, with the result of saving much of the time now taken up by the ordinary method.

Mr. A. GORDON SALAMON wished to call attention to one other point to which Mr. Andreoli had not referred, namely, a most ingenious and valuable method of his for uniting glass piping and lead fittings, and which consisted in simply binding copper wire tightly round the glass tube, when it could be easily soldered to the lead in the ordinary way.

The CHAIRMAN understood that the results obtained by Mr. Andreoli's apparatus were a very marked improvement on the yield hitherto given by other apparatus.

Mr. GABRIEL ANDREOLI, in replying on behalf of his father, said he would be most happy to add a complete bibliography of ozone to his paper if it would be desired by the Society. It had been objected that the paper was merely a list of possible applications. Quite true; but some of those applications had already been mentioned in Dr. Frölich's admirable paper; and if the learned German electrician was able to foresee a future for ozone and believe in the commercial applications, even with a lower yield of ozone than manufacturers were now able to obtain from the Andreoli apparatus, surely they were justified in mentioning them again, and also some other applications. They had been reproached also on the question of the cost of ozone; against that, he would point out that the ozone produced in their apparatus was cheaper than in all the other ones. It had been found that ozone would do what oxygen could not do; and if, as in the case of the oxidation of oils, for instance, they saved time by utilising ozone, that would more than compensate for the expense. It is certainly most regrettable not to be in a position to state what had been the results of commercial experiments, but it took time to induce manufacturers to try ozone, even when they had nothing to spend for the ozonisers, transformers, and even dynamos, which they might have at their disposal during one or two months for 1 to 5 or 10 h.p. installations. It has also been said that in the oxidation of wines and spirits, ozone would have a destructive as well as a beneficial effect, and that at a certain point one would get acetification; but there was no process which, unless carried out judiciously, would prove to be a success. No excess of ozone was required to mature wines, and it was out of question that ozone could be applied in that way. It must be understood that they never said a word about the purification of sewage by ozone, and that the sterilisation of water which had been mentioned in the present paper must be considered, not as a scheme, but simply as a highly

interesting fact which showed the germicidal action of ozone on the pathogenic and non-pathogenic bacteria which exist in water. Who would deny, for instance, the beneficial effects of sterilisation by ozone of the water for drinking purposes on board liners and also in the Colonies? The object of the paper really was to point out that ozone could be used industrially; and if the writer of this paper had only facilitated the getting together of detailed information on the production of ozone on a commercial scale, and thus drawing closer and more general attention to it, he would not have failed. As to the bleaching of beeswax and bones, he was sorry that he had not referred to it; he was quite aware that such use of ozone was practicable. As to the influence of points, it was a recognised fact that they facilitated the high tension discharge, and this did not require discussion. Some analyses referred to in the paper were made by Dr. L. T. Thorne, who was quite competent to defend them; the figures referring to 34.5 grms. and 40 grms. show the results obtained by Prof. W. Ramsay.

*Meeting held on Monday, February 15th, 1897.*

DR. R. MESSL IN THE CHAIR.

## ELECTRO-DEPOSITION AND RECOVERY OF GOLD.

BY E. ANDREOLI.

THE cyanide process cannot be a complete success without a satisfactory method of recovering gold from its solution. Zinc was the only medium used for separating the precious metal, until Messrs. Siemens and Halske set to work to apply the electrolytic method to the deposition of gold from its cyanide solution. The electro deposition of gold from its cyanide solution does not *prima facie* appear to be an operation which presents any great difficulty, and to the uninitiated, it comes to the same thing as electro-plating. There is, however, a great difference between treating concentrated cyanide of potassium solutions carefully prepared and containing a large proportion of gold, the strength of which is kept up by a gold anode, at an electro-plating works, and electrolytically treating 100 to 150 tons of a very weak solution of cyanide containing a very small proportion of gold. In the former case, one has to coat metallic articles with a layer of gold of a certain thickness; in the latter, one has to practically exhaust the solution while it is passing through the tanks.

The treatment of 100 tons of solution per day of 24 hours represents a circulation of more than 4,166 litres per hour, or almost 70 litres per minute. A mode of circulation must be adopted which allows a constant and perfect contact of the electrolyte with the plates. Then the arrangement of the plates in the tanks must be such that they are not too far apart, and that the electro-motive force must be as low as possible, and therefore ensure economy of working.

Now, assuming that one has an electrolyte which is a good electrical conductor, that the electro-motive force is not too high, and that the best system for arranging the electrodes in the vats and for circulating the liquid between them at a rapid rate has been adopted, what material is to be used for the construction of the anodes? All the metals, without exception, dissolve at the positive pole in a cyanide of potassium solution; the best carbon will soon be attacked and disintegrated. Iron is, of all the metals, the only one which resists somewhat when acting as an anode in a cyanide of potassium solution; still, it dissolves. Complicated reactions take place, and the electrolyte is contaminated with all sorts of impurities.

It has been my good fortune to find an anode which is neither carbon nor metal, and which cannot be destroyed under the corrosive action taking place at the positive pole in a cyanide electrolyte, and which does not decompose or spoil the solution. I must say, however, that it is not a discovery resulting from my researches and studies, it is simply the result of chance. I was making experiments on

what I call secondary electrolysis, when I noticed that, having put in the central compartment of a tank containing a gold and potassium cyanide solution, a piece of perforated lead close to the negative partition of the compartment, the lead, which in this case acted as an anode, had become brown. I soon ascertained that the plate was covered with a strongly adherent coating of peroxide of lead. But for this observation, I am sure I should never have thought of using this substance, which I had already unsuccessfully tried as an anode in a chlorine solution. There is therefore, no other merit attached to this discovery except my having noticed the formation of peroxide of lead, on a lead plate in the course of experiments on the deposition of gold, which were very satisfactory on a laboratory scale, but could not practically be carried out in the gold districts where the use of porous partitions is an impossibility.

I commenced then a long series of tests which all proved the excellence, the solubility, and the insolubility of these anodes when properly made, and I started electrolytic vats, each containing 30 large anodes. These plates were formed according to the Planté method, which means that they require a very long treatment; but at present I prefer to use a solution of plumbate of soda, in which they are rapidly coated with peroxide of lead, then withdrawn, washed, and placed in a strong cyanide of potassium solution, where, under a heavy current, they become hard and have a good crystalline appearance. The first thing I did when I had these anodes at my disposal was to use them to deposit gold on zinc plates. It was better and more rapid than the usual deposition on zinc shavings, but I did not consider it at all good; besides, in my mind, there was a great drawback to this electro-deposition, where each anode had to be placed between two cathodes. It can be realised how long it must take to disconnect, say, only 1,000 cathodes, and then to replace them by another 1,000 plates, and this is still worse if one has to withdraw the anodes and to put in fresh ones. What then if the plates have to be framed? I need not insist on this waste of time and labour, and to this must be added that, if the anodes are soluble, the liquid is spoilt and the tanks have to be cleaned. I may here point out that with my insoluble peroxide anodes the gold cyanide solution is as clear after as it was before treatment.

In my mind, the real problem of the electrolysis of a large volume of gold cyanide solution is to have as few plates as possible and a large surface on which to deposit the gold. I constructed a tank with two grooves cut in the bottom, which were filled with mercury. My cathodes were amalgamated perforated copper plates, standing in the mercury in the grooves, doing away with terminals and connecting bars. These cathodes were thus all in contact with the mercury, which was itself, by means of a copper strip, connected to the negative pole of the dynamo. Each plate could thus be withdrawn and replaced without the slightest trouble. There were in the tank about 50 perforated cathodes, forming an enormous active surface, and, instead of 51 anodes, I used only 5 to 6 peroxide of lead plates. The mercurial surface with which the gold solution had to be in constant, intimate, and perfect contact, under the action of the electric current, was enormous, but the quantity of mercury in each tank was very small, and the absorption of the gold by the amalgamated plate, which formed a sort of electric filter, was practically complete. Four of these tanks were capable of doing the work of eight ordinary tanks. This was a great advance, but I was soon disappointed when I was told that nobody in mining districts would care much for adopting such a process, which involved too much trouble in distilling the mercury and cleaning the plates in order to recover the gold amalgamated with it.

I firmly believe, however, in this method, which allowed me to rapidly and very efficiently exhaust the solution in a comparatively very small installation. I had, however, to find something else and something better which would suit the wants of mine managers. I commenced to deposit the gold on iron plates, which take gold much more readily than lead. Gold adheres better to iron and steel than to any other metal, and I was rather puzzled as to how to recover the gold from these cathodes, when it struck me that molten lead, which alloys so easily with gold in crucibles and

cupels, ought equally to absorb it from my gilded cathodes. I dipped a few pieces of iron coated with gold in a crucible containing molten lead, and after a very short time I had the satisfaction to withdraw them deprived of every particle of gold. This is how I recover the gold now. I deposit it on iron cathodes, from which I strip the gold by dipping them for about one minute in a bath of molten lead or bismuth kept at a proper temperature. An alloy is instantaneously formed which becomes richer and richer in gold, and which can easily and economically be cupelled, with the result that the bullion is absolutely pure.

To give you an idea of the extent of the application of electrolysis to the recovery of gold, I will quote the following lines, written in October 1896 by Mr. Charles Butters, Manager of the Central Rand Ore Reduction Company, who has started the Siemens and Halske process in the Transvaal:—

"We have been treating for the past two years 3,000 tons a month at the Worcester Mine. We have treated at this property about 70,000 tons of material, and the works are a complete success. This success was followed up by the introduction of the process into several other properties. We have been treating about 25,000 tons a month for several months past with most satisfactory results. There will be under treatment on the Witwatersrand by this process, about the beginning of next year, 100,000 tons a month of tailings and slimes. We have been treating at the Robinson Mine 6,000 tons of slimes per month, handling 800 tons of cyanide liquor per day, containing in the liquor to be precipitated from 4 dwts. a ton down to 15 and 18 grains, and this liquor is precipitated from 4 dwts. down to 8 or 9 grains, and from 18 grains down to 3 or 4 grains."

DR. C. A. KOHN IN THE CHAIR.

## EFFICIENCY OF AN ELECTROLYTIC CELL.

BY F. HURTER, PH.D., AND B. ZAHORSKI, PH.D.

IN a previous paper read before this Section by one of us, a formula was discussed which expressed the efficiency of an electrolytic cell, i.e., that fraction of the energy consumed by the cell which was converted into the desired potential chemical energy.

That formula was—

$$\frac{a \cdot e}{V}$$

wherein  $e$  represents the so-called back electro-motive force corresponding to the products which are desired, whilst  $V$  represents the actual electro-motive force measured at the terminals of the cell. The factor  $a$  was not discussed in that paper at any length, and it is the purpose of the present paper to communicate the results of a number of investigations which have been made in the central laboratory of the United Alkali Co., part of which were communicated to the Liverpool Physical Society, but have not been published. Most of the investigations we are about to communicate have, however, been made since that paper was read.

The factor  $a$  in the above formula represents the fraction of the electro-chemical equivalent of the desired substance actually obtained per ampère.

Theoretically, we ought to obtain for every ampère of current one electro-chemical equivalent of the substance. In many carefully arranged electrolytic experiments the theoretical yield is actually obtained. In many practical processes of electrolysis the yield approaches closely to the theoretical, but in many other processes the yield per ampère is very much less than that calculated by Faraday's law. The theoretical yield is easily approached in all processes where the separated ions are deposited as solids or removed as gases; such is the case in the process of copper-refining, in a well-conducted electrolysis of zinc salts, &c., &c. But in such processes, where the products of the electrolysis remain in solution, where so-called secondary reactions take place, the newly-formed products take part in the conduction of the current; and, from the manufacturer's point of view, the current which produces other than the desired reaction is wasted.

The aim of our investigations is to trace quantitatively this "wasted" current, and to connect it with previously well-known phenomena in such a manner that the whole quantitative course of a given electrolytic process might be precalculated with a similar degree of accuracy as we now can precalculate the necessary terminal voltage for a given process.

We desire at once to state that it would be presumption on our part if we asserted that we have solved the problem, but we have at any rate succeeded in making a fair beginning in the science or precalculating, so to say, the crude outline of the quantitative course of the electrolytic changes, i.e., the current efficiencies.

In order to prevent misunderstanding, we wish to present in the most elementary manner our methods of calculation, and to recall as concisely as possible the essential features of the phenomenon known as the migration of ions. There are no elementary English treatises on practical electrolysis which deal with the subject. Even a modern German treatise on the subject—viz., "Handbuch der Electrochemie," by Ahrens (1896)—does not contain a chapter on the application of the phenomena of migration, and that word cannot be found in the index. There is not, to our knowledge, any scientific or technical treatise which indicates how the current efficiency might be estimated by means of the known velocities of ions, and this must be our excuse for troubling you with a few elementary remarks on the subject.

In order to fix our ideas, let us assume an electrolytic cell, in which we decompose potassium chloride. The instant we close the electric circuit, chlorine is evolved at the anode, hydrogen at the cathode; and we know by Faraday's law that after 100 ampères have been passed through the cell, there will be 100 (electro-chemical) equivalents\* of chlorine liberated at the anode, and 100 equivalents of hydrogen at the cathode, corresponding to the decomposition of 100 equivalents of potassium chloride.

We are all acquainted with the explanation of the process as given by Grothus, viz., the exchange and passage in opposite directions of the ions from one molecule to its neighbour. This explanation demands that after the passage of 100 ampère seconds through the cell there should be 50 equivalents of chlorine more on the anode side of the cell than there were before, and 50 equivalents more potassium

\* Throughout this paper the term "equivalent" means an electro-chemical equivalent.

on the cathode side than were there before, including in the counting the free chlorine as well as the combined on the one side, and the potassium present as hydrate as well as in the form of chloride on the other side. This is usually represented by the following diagram:—

DIAGRAM No. 1.  
BEFORE ELECTROLYSIS

AFTER ELECTROLYSIS

4. Chlorine Liberated      4K Liberated  
2 " more in compartment    2h more in compartment  
ANODE                                  CATHODE

If the experiment be made with potassium chloride, it is found that the increase of chlorine and potassium in the respective compartments is very nearly 0.5 of the amount of the substance liberated, but if the experiment be made with sodium chloride, then the results are different, *viz.*, in a saturated solution we find an increase of 0.648 equivalents of chlorine in the anode compartment and 0.352 of sodium in the cathode compartment per equivalent liberated. It would appear as if, for 100 ampère seconds passed through the cell, 35 equivalents of salt had been decomposed at the anode, liberating there 35 of chlorine and causing 35 sodium to migrate towards the cathode, whilst 65 equivalents of salt had been decomposed at the cathode, liberating 65 of sodium and causing 65 of chlorine to migrate into the anode compartment.

Hittorf, to whom we are indebted for all the leading thoughts on which our work is based, has established, by an exhaustive series of experiments, that for each salt there is such a transport ratio, which is slightly affected by the concentration of the solution, but is not affected by the material or distance of the electrodes, nor by the material or number of diaphragms employed, nor by variation of temperature within certain narrow limits. To Hittorf is also due the explanation of the phenomenon by ascribing to the various ions different velocities. Thus, from Hittorf's numbers we find that if sodium travels with a velocity 1, then chlorine travels with a velocity  $\frac{0.65}{0.35} = 1.85$ .

In this respect the electrolysis of sodium chloride differs very materially from that of potassium chloride, owing to the fact that potassium and chlorine travel nearly with equal velocities, whilst sodium and chlorine travel at very different rates. The technical importance of this fact we shall refer to later.

Hittorf also foresaw that a connection must exist between the relative conductivities of the solutions and their transport ratios. But an accurate determination of the conductivity of a solution was almost an impossibility in Hittorf's time, and it was reserved for Kohlrausch to devise the elegant method for the determination of the conductivities of saline solutions which enabled this relation to be established. Kohlrausch's discoveries in this direction resulted in showing that the conductivity of a salt was the sum of two constituent parts, *viz.*, the conductivity of the anion and the conductivity of the cation, and that the same anion or cation had the same conductivity in a great number of its salts.

These relative conductivities were found to bear the same relation to each other as the transport ratios of Hittorf; they were, in fact, a different numerical expression of the same fundamental phenomenon—the different velocities of the ions.

Thanks to the efforts of Hittorf, Kohlrausch, Wiedemann, and many other observers, we are now in possession of a

table of the relative conductivities of the various ions, by means of which we can replace lengthy tables of transport ratios for dilute solutions.

The following is such a table (Wiedemann):—

TABLE I.

Cations.		Anions.	
K.....	60	Cl.....	62
Na.....	40	J.....	63
Li.....	33	NO <sub>3</sub> .....	58
NH <sub>4</sub> .....	60	ClO <sub>3</sub> .....	52
H.....	290	ClO <sub>4</sub> .....	51
Ag.....	52	OH.....	165

The numbers given in the table may thus be used for calculations (1) of the molecular conductivities of dilute solutions.

Thus the molecular conductivity of NaHO is the sum of the numbers (Na = 40) + (OH = 165), or 205, whilst for a solution of sodium chloride of similar concentration the molecular conductivity is only 40 + 62 = 102.

Thus a dilute salt solution conducts only half as well as a solution of caustic soda.

(2.) We can calculate from these numbers the transport ratios. Thus the transport ratios for sodium chloride are for—

$$\text{cation } \frac{40}{40 + 62} = 0.392; \text{ anion } \frac{62}{40 + 62} = 0.608.$$

It is thus very easy to represent for dilute solutions the quantitative results, not only with respect to Faraday's law, but also with respect to alterations in the concentrations and constitution of the solutions in the immediate neighbourhood of the electrodes after the passage of a given current, such that the constitution of the solution is not materially altered.

In order to show how this is best done, let us represent the electrolysis of a salt solution diagrammatically by means of these numbers. We have, after the passage of a certain current (102 ampère seconds),—

DIAGRAM No. 2.

40 NaCl were decomposed at the anode; the sodium of these migrates towards the cathode.

62 NaCl were decomposed at the cathode, the chlorine of which migrates towards the anode.

There are liberated 62 + 40 Cl at the anode; there are liberated 62 + 40 Na at the cathode; and since the current is measured by the ions liberated, the current passed through the cell is the sum of all the migrated ions, *viz.*, 62 + 40 (ampère seconds).

It is important to remember that the current can always be measured by the sum of the number of ions transported towards both electrodes.

When, however, the passage of the current produces a new electrolyte, as it does in the case of the electrolysis of potassium chloride or sodium chloride, then the question arises, How can we foretell approximately the further course of the electrolysis when the constitution of the electrolyte has been materially altered?

Let us again suppose a cell, divided by a diaphragm and containing a solution of common salt. Let a certain amount of current be passed through the solution, and, in consequence, let the cathode compartment contain a mixture of salt and

sodium hydrate. Since sodium hydrate is much the better conductor of the two, a great amount of the current will electrolyse sodium hydrate with reproduction of the same amount of sodium hydrate, and with a corresponding migration of hydroxyl ions into the anode compartment. Only a part of the current will electrolyse sodium chloride, with production of additional sodium hydrate in the cathode compartment, and with corresponding migration of chlorine ions from the cathode compartment to the anode. At the same time some sodium ions will migrate from the anode compartment into the cathode compartment and increase the amount of sodium hydrate there formed.

The increase in the number of equivalents of sodium hydrate in the cathode compartment is due to, first, the emigration of chlorine ions from the cathode compartment towards the anode, and secondly, to the immigration of sodium ions into the cathode compartment from the anode compartment. If we add these two numbers of newly formed equivalents of sodium hydrate and divide by the ampères which have caused this change, then we have calculated the current efficiency of that particular cell. We have thus reduced the problem of calculating the current efficiency to a problem in calculation of migration of ions.

In order that the principle of the calculation may be more clearly grasped, let us assume that, by reason of the given, but at present unknown, mixture of sodium hydrate and sodium chloride in the solution in the cathode compartment, there are 20 equivalents of hydroxyl emigrating together with 80 equivalents of chlorine from the cathode compartment. No new formation of sodium hydrate accompanies the emigration of the 20 equivalents of hydroxyl, but to the emigration of 80 equivalents of chlorine corresponds the formation of 80 equivalents of sodium hydrate. In addition to these 80, there will be a certain number of sodium ions migrating from the anode to the cathode. That number is easily calculated by a simple proportion, thanks to the principle of constant velocities of the ions.

We know that for 62 chlorine which migrate in one direction, 40 sodium migrate in the other; hence, for the 80 which we assumed to migrate in the above case, there will be immigration of—

$$\frac{80 \times 40}{62} = 51.5 \text{ sodium.}$$

Similarly we know that for a migration of 165 hydroxyl ions there will be a contrary migration of 40 sodium ions, and consequently the migration of 20 hydroxyls involves a migration of—

$$\frac{20 \times 40}{165} = 4.85 \text{ sodium ions.}$$

The total number of sodium ions newly formed, and immigrated into the cathode compartment, is therefore—

$$80 + 51.5 + 4.85 = 136.35.$$

But we also know that the sum of all the migrations measures the current. Hence the value of the current is—

$$\begin{array}{rcl} 20 + 80 & 51.5 + 4.85 & \\ \text{Anion} & + & \text{Cathion} \\ \text{migration.} & & \text{migration.} \end{array} = 136.35.$$

and the current efficiency in that case would be—

$$\alpha = \frac{136.35}{156.35} = 0.875.$$

We hope to have thus clearly explained the calculation of a current efficiency by means of the relative velocities of migration.

But in doing so we have assumed a relative migration of 20 hydroxyl ions and 80 of chlorine ions, and such an assumption is of no use except as an illustration.

To render the principle useful, we must be able to state how the current will divide itself in the cathode compartment between the sodium hydrate and the sodium chloride contained therein in known proportions.

This problem is readily solved for dilute solutions. In all such solutions the conductivity is simply the sum of the conductivities of the several ions they contain.

Thus, if a solution contain  $M$  molecules of sodium salts, of which  $x$  are sodium hydrate and  $(M - x)$  are sodium chloride, then the conductivity would be—

$$102 (M - x) + 205 x,$$

and the current would divide itself between salt and caustic soda (if we disregard the influence of the electro-motive force of polarisation) in the ratio—

Salt.	Caustic Soda.
$102 (M - x)$	$205 x$

To the former current corresponds a migration of  $62 (M - x)$  chlorine and  $40 (M - x)$  sodium; to the latter current corresponds a migration of  $165 x$  hydroxyls and  $40 x$  sodium; hence the current efficiency is—

$$\alpha = \frac{102 M - 62 x}{102 M + (205 - 102) x}$$

This formula for the current efficiency is, however, only valid for a short moment, since on continuing to pass the current,  $x$  continually increases, and  $M$  also undergoes alterations. It is easy to change the above formula into a differential equation. If the current be  $C$  ampères, the amount of sodium hydrate produced will be in the time  $dt$ —

$$dx = \alpha C dt.$$

Substituting for  $\alpha$  its value, and integrating, we obtain the efficiency for the whole current needed to produce  $x$  mols. of sodium hydrate in the cathode compartment, which at the beginning contained only salt.

Thus, for dilute solutions, the problem of calculating the current efficiency is reduced to a simple problem of calculating migration or conductivity phenomena.

But to the technologist the knowledge of the behaviour of very dilute solutions is of but small value. He is concerned as a rule with concentrated solutions, for which the simple laws above stated do no longer hold good, and the methods of calculation just explained can only furnish a hint towards an investigation of the problems of precalculating the current efficiency for any given cell filled with concentrated solutions.

The first question is, naturally, How do the transport ratios change with the concentration of the solutions? This has been ascertained by various investigations. We give in Table II. a few of the results for such salts as have a particular interest in connection with our experiments.

TABLE II.

As regards the alteration of the transport ratios with temperature, but few observations are yet at our disposal. At ordinary temperatures there is but little change.

It has also been proved that the transport ratios are independent of the material of which diaphragms are made, porcelain giving the same result as tinsnes or parchment. They are also independent of the nature of the electrodes.

The net result of the investigations represented by the table is that, as far as transport ratios in concentrated solutions are concerned, they are sufficiently constant to permit their use for technical calculations.

The next point to consider is, How can we calculate the ratio in which a given current divides itself among different electrolytes in one concentrated solution?

For this purpose, let us imagine a trough divided lengthways by a partition, so that one half of the trough is filled with, say, sodium chloride solution, and the other half with, say, sodium hydrate solution. Let the ends of the trough be formed by two platinum plates, which serve as electrodes. Let a current be now sent through the trough, such that the plates show a terminal potential difference of  $V$  volts.

Let the electro-motive force needed for the decomposition of the salt be  $E_1$  and the conductivity of the solution  $C_1$ ; and, similarly, let the electro-motive force for decomposing sodium hydrate be  $E_2$  and its conductivity  $C_2$ ; then we have the currents  $A_1$  and  $A_2$  passing through the salt and caustic compartment respectively—

$$A_1 = C_1(V - E_1)$$

$$A_2 = C_2(V - E_2).$$

The total current is thus represented by—

$$A_1 + A_2 = C_1(V - E_1) + C_2(V - E_2);$$

the fraction travelling over salt is:—

$$\frac{C_1(V - E_1)}{C_1(V - E_1) + C_2(V - E_2)}$$

and if we consider this fraction of the current as the only useful one, then it also represents the current efficiency of the given arrangement. If the two solutions are such that they contain an equal number of molecules per litre, and the sectional areas of the two parts of the trough are  $M_1$  and  $M_2$ , the number of molecules of the constituents will be in proportion  $M_1$  and  $M_2$ , and the conductivities grow with the areas; hence we have the current efficiency—

$$\alpha = \frac{M_1 C_1 (V - E_1)}{M_1 C_1 (V - E_1) + M_2 C_2 (V - E_2)}$$

or—

$$\alpha = \frac{M_1}{M_1 - M_2} \cdot \frac{C_1}{C_1} \cdot \frac{(V - E_2)}{(V - E_1)}$$

If we now remove the partition and allow the solutions to mix, the formula will still hold good if the conductivity of the mixture is equal to the sum of the conductivities of its parts.

In that case the above formula represents the current efficiency with respect to the one constituent in an open cell containing a mixture of electrolytes.

It is readily seen that this efficiency becomes perfect, *i.e.*, equal to 1, only when the term—

$$M_2 \cdot C_2 \cdot \frac{(V - E_2)}{(V - E_1)} = 0$$

vanishes. And this can only happen in two ways either if  $M_2$  itself is 0, *i.e.*, if only one electrolyte is present; or if the difference  $(V - E_2)$  becomes 0, *i.e.*, if the terminal voltage can no longer decompose the substance  $M_2$ .

The current efficiency is zero, if the difference  $(V - E_1)$  becomes zero, *i.e.*, if the terminal voltage is not great enough to decompose the substance  $M_1$ .

If the terminal voltage is increased, the fraction  $\left(\frac{V - E_2}{V - E_1}\right)$  tends towards unity, and in that case the current efficiency tends towards a limiting value—

$$\alpha = \frac{M_1}{M_1 + M_2} \cdot \frac{C_2}{C_1}$$

The increase of the terminal voltage means a high current density, and the formula shows that if  $E_1 > E_2$ , a higher current density will increase the current efficiency. This explains why, for certain processes, a better energy efficiency is obtained with a higher voltage than a lower one, and confirms what has often been observed—that of two cells, the one using the lower terminal voltage is not necessarily the best.

This limiting value of the current efficiency is in most cases the only value that can at all be calculated, since in complicated processes we know but little of the real values of the electro-motive forces of polarisation. Consequently, in what follows we give for comparison with actual experiments only the limiting values of the calculated current efficiencies.

In order to test the applicability of these principles we made two solutions, one of potassium chloride and one of potassium hydrate, containing exactly 3 grm.-mols. of the substance per litre.

We estimated carefully the conductivity (by Kohlrausch's method) of the pure solutions of potassium chloride and potassium hydrate, and of mixtures of these at various temperatures. We give in Table III. the details.

TABLE III.

\* Amperes per volt per litre.

The net result of the investigation is, that the conductivity (amperes passing per volt through one litre) for a solution of KCl containing 223.34 grms. KCl per litre (3 mol.) is, at the absolute temperature  $T$ ,—

$$C_1 = 0.04263 T - 9.244,$$

and that a KHO solution, 168 grms. per litre (3 mols.), is  $C_2 = 0.0767 T - 18.308$ , and for mixtures containing  $x$  volumes of such a potassium chloride solution, and  $1 - x$  volumes of a potassium hydrate solution, the conductivity at any absolute temperature  $T$  is—

$$C = (0.0767 - 0.0341 x) T + 8.384 x - 18.308;$$

that is, at any temperature  $T$  the conductivity of the mixture is the exact arithmetic mean between the conductivities of the two solutions at the same temperature.

If the conductivity of the 3-molecule potassium chloride solution is chosen as unit, that of a corresponding potassium hydrate solution at the same temperature is 1.623. The conductivity of a mixture of  $(100 - x)$  volumes of the one with  $x$  volumes of the second is very nearly—

$$\frac{(100 - x) + x \times 1.623}{100}$$

or, otherwise expressed, the conductivity of the mixture is very nearly the sum of the conductivities of its constituents; so that, on the principles we have just explained, the current efficiency for the decomposition of the potassium chloride in such a mixture in an open cell would be—

$$\alpha = \frac{100 - x}{(100 - x) + x \times 1.623} \frac{(V - E_1)}{(V - E_2)}$$

A number of various mixtures of these solutions were next subjected to electrolysis in a cell without diaphragm

between platinum electrodes. The gaseous products of the electrolysis were measured and analysed. The volume of detonating gas evolved in a voltmeter by the same current in the same time was also noted. From the given data we calculate the amount of oxygen which the current evolved in the cell and in the voltmeter; this gives the current efficiency for oxygen for the given mixture of KCl and KOH solution; the difference between that and 100 is the chlorine efficiency.

Thus, on subjecting a mixture of 90 c.c. of the KCl solution and 10 c.c. of KOH solution to electrolysis, we found 11.4 c.c. of oxygen evolved, whilst in the voltmeter 99 c.c. of detonating gas were found, equivalent to 33 c.c. of oxygen. Thus the current efficiency for oxygen is  $\frac{11.4}{33} = 34.5$  per cent., and, by difference, the efficiency for chlorine is 65.5 per cent.

The Table IV. exhibits the details of these experiments and the efficiencies actually found, compared with the results of a calculation of the limit of current efficiency based upon the principle explained, *viz.*, that the current divides between the two salts in proportion to conductivity, disregarding the difference in electro-motive force.

It will be seen that the limiting current efficiencies calculated from the conductivities do not agree with those actually obtained by experiment. This is strikingly exhibited by the diagram. The experiments were carefully made, but they are of course influenced by the formation of secondary products, particularly hypochlorite, the presence of which makes itself felt at the cathode, to which it only moves by diffusion and agitation.

This is shown in the column "Reduction at Cathode," which indicates the percentage of hydrogen which was not evolved in the cell owing to reduction of hypochlorite at the cathode.

The liquid surrounding the anode rapidly becomes richer in oxygen compounds than the given composition of the electrolyte indicates, since from 70 to 90 per cent. of the current produces chlorine, which at once is absorbed as hypochlorite. Thus we must expect the oxygen evolution to be greater than would be the case if a uniform composition of the solution could be maintained.

As Hittorf already pointed out, the way in which the current distributes itself between two electrolytes can only really be found by migration experiments, and such are very difficult to make and very tedious.

The result of these experiments teaches us that in an open cell the calculation of the current efficiency from the assumed conductivities is a higher limit for the production of chlorine or hypochlorite; that the current seems to electrolyse more readily the potassium hydrate than the calculation from conductivities would indicate.

In a similar manner the conductivities of mixtures of sodium chloride and sodium hydrate were determined by Mr. Auer. The net result of his measurements is given in Table V.

From those results it appears that very approximately the conductivity of the mixtures is again the arithmetical mean of the constituent parts. If the conductivity of the sodium chloride solution is taken as unit, that of the corresponding NaHO solution is 1.58.

The following experiments to ascertain the current efficiency for sodium hydrate with various mixtures of NaCl and NaHO solution were made:—

1. In a porous porcelain cell filled with a solution of sodium chloride containing 5 grm.-mols. per litre, a platinum anode was placed. A beaker was filled with the same solution, and a platinum cathode surrounding the porous pot was employed. The current was passed until the outside compartment contained 5 grms. NaHO per litre. The current efficiency varied from 0.91 to 0.93.

TABLE V.  
Conductivities, 16°.

0	5	0.3284	3.045	15.7	3.063	3.063

$$* C = 0.388 (M - x) + 0.612 x.$$

2. The same arrangement was used, but the cathode was surrounded with a solution containing 3.15 grm.-mols. of NaCl and 1.85 grm.-mols. of NaHO. The current efficiency was found to be from 0.369 to 0.416.

3. The same arrangement was used, but the solution in the cathode compartment contained 4.75 grm.-mols. of NaHO and only 0.25 grm.-mol. of NaCl per litre. The current efficiency was found to vary from 0.10 to 0.16.

In all these experiments the current was measured by a copper voltmeter, and the increase in alkalinity of the solution ascertained, from which two data the current efficiency was calculated.

These experiments cannot be compared with the formula for the limit of current efficiency given for the open cell, where questions of migration do not play any part. In these experiments a diaphragm was used, and the electrolyte in the anode compartment differed from that in the cathode compartment. Hence the phenomena of migration must be taken notice of. This is done as follows:—

If the transport ratio for a concentrated solution (5 grm.-mols.) of sodium chloride is taken as Hittorf's figure = 0.352, then the velocity of the sodium ion is 0.35, that of chlorine 0.65. Since the relative conductivity of a 5-molecule sodium hydrate solution is by our measurements 1.58 times as great, the relative velocity of the hydroxyl ion must be—

$$1.58 - 0.35 = 1.23.$$

Hence the relative velocities of the ions in this concentrated solution may be taken as—

Na.....	0.35	1.00
Cl.....	0.65	1.86
HO.....	1.23	3.50

and the transport ratio for NaHO are 0.222 and 0.788.

In the cathode compartment the current divides for the limiting condition as—

$$M_1 : M_2 \frac{C_2}{C_1}, \text{ i.e., as } M_1 : 1.58 M_2$$

if  $M_1$  and  $M_2$  are the number of molecules of sodium chloride and sodium hydrate respectively.

The current  $M_1$  produces  $M_1$  ions of sodium, which count as new sodium hydrate. The decomposition of the sodium hydrate in the cathode compartment produces no new sodium hydrate, but to the emigration of hydroxyls corresponds an immigration of sodium. The amount of sodium hydrate thus brought into the cathode compartment is  $0.222 M_2 \frac{C_2}{C_1} = 1.58 \times 0.222 \times M_2$ . Hence the current efficiency is, for sodium hydrate,—

$$\alpha = \frac{M_1 + 0.350 M_2}{M_1 + 1.58 M_2}$$

Comparing this with the efficiency for the open cell viz.,—

$$\alpha = \frac{M_1}{M_1 + 1.58 M_2}$$

we see at once the beneficial influence of the diaphragm.

The following Table VI. compares the results of actual experiments with the efficiencies so calculated, and again indicates, what the previous experiments with potassium solutions have shown, that the calculated results are, higher limits for the production of soda and chlorine; that more current travels over NaHO than the calculation from conductivity would lead us to suppose.

TABLE VI.

Electrolyte Molecules per Litre in Cathode Compartment.		Efficiency.	
NaCl( $M_1$ ).	NaOH( $M_2$ ).	Actual.	Calculated.
5.00	0	0.91—0.93	1.000
3.15	1.85	0.37—0.42	0.610
0.25	4.75	0.10—0.16	0.209

Electrolyte in anode compartment: saturated solution of NaCl.

These results show also that if the cathode compartment contains only sodium hydrate, the current efficiency falls very low. It is well known that many inventors have constructed cells which should contain in the cathode compartment pure caustic soda solutions, and the investigation of the current efficiency of such cells has consequently commanded our attention at various times.

Some of our older experiments (made by Mr. Auer) may find a place here.

Into the anode compartment was placed a solution of common salt containing 312 grms. NaCl per litre. Into the cathode compartment were placed caustic soda solutions of various concentrations, the current being measured by a copper voltmeter. The following Table VII. exhibits the results:—

TABLE VII.

Solution near Anode.	Solution near Cathode.	Observed Efficiency.
312.6 grms. NaCl per litre	80.0 grms. NaOH per litre	0.150
312.6 " "	4.0 " "	0.241
312.6 " "	1.0 " "	0.247
312.6 " "	4.0 " "	0.334
312.6 " "	2.0 " "	0.233
312.6 " "	0.8 " "	0.250
Mean .....		0.250

In this case the extreme efficiency would be theoretically simply the transport ratio for sodium in caustic soda, which for dilute solutions is, according to Kuschel, about 0.20.

It will be seen that the results are variable—some higher, some lower. Mr. Auer at that time thought the variability was due to the mode of filling the cell. If the diaphragm was moistened with salt the efficiency was good; if the caustic was first put in and the diaphragm soaked therewith the efficiency would be bad.

Two experiments which he made to test this point gave the following results:—

Electrolyte used.		Current Efficiency.
Anode Compartment.	Cathode Compartment.	
Concentrated NaCl solution, filled first.	NaOH solution, 80 grms. per litre, filled last.	0.43
Concentrated NaCl solution, filled last.	NaOH solution, 80 grms. per litre, filled first.	0.22

We therefore repeated these experiments, but under such conditions that the diaphragm was used for some time and got into a condition of stability as to the composition of the solution filling its pores, and then rapidly replaced the solutions one after the other, each operation being a quantitative experiment. Thus we found the following results:—

TABLE VIII.

Time.	Cu deposited in Voltmeter.	NaOH formed.	Current Efficiency for NaOH.	Chlorine as NaClO and NaClO <sub>2</sub> .	Current Efficiency for Cl combined.
	Grms.	Grms.	Per Cent.	Grms.	Per Cent.
60	1.187	0.240	16.0		
60	0.943	0.228	19.1	0.614	58.1
60	1.102	0.284	20.4	0.701	57.7
120	2.161	0.552	20.1	1.508	62.3
300	5.435	1.528	22.1	3.980	60.6

Porcelain diaphragm.

Electrolytes:—

Anode ..... NaCl solution (saturated).  
Cathode ..... NaOH solution (normal).

It will be seen that after the stationary condition of the diaphragm had been reached the experiments gave fairly constant current efficiencies, which are nearly equal to the transport ratio = 0.20 (Kuschel).

This table also gives the amount of chlorine which was found in the anode compartment as hypochlorite and chlorate.

If the current efficiency in such a cell really depends upon the migration or transport ratio only, then a totally different result must be obtained if the cathode compartment be

filled with another solution, the transport ratio of which is different. In order to test this, the cathode compartment was filled with Na<sub>2</sub>CO<sub>3</sub> solution, the transport ratio of which is given by Kuschel as 0.17.

The following results were obtained, viz.:—

TABLE IX.

Time.	Cu deposited in Voltmeter.	NaOH formed.	Current Efficiency.
	Grms.	Grms.	Per Cent.
60	1.180	1.089	72.3
60	1.212	0.744	48.5
60	1.147	0.720	50.0
60	0.580	0.368	59.1

Porcelain diaphragm.

Electrolyte:—

Anode ..... NaCl solution (saturated).  
Cathode ..... Na<sub>2</sub>CO<sub>3</sub> solution (normal).

These show that after the diaphragm had assumed a stationary condition, the results obtained were about 0.5, clearly pointing to the transport ratio of carbonate of soda.

These experiments show that the same cell will give a vastly improved yield, if working for carbonate of soda, than if working for caustic—a result which Mr. Hargreaves avails himself of, and which, he held, could not be explained by the migration theory.

So far, we have dealt only with the cathode compartment and the current efficiency referring thereto. We must now cast a glance at the anode compartment, and try to obtain an insight as to what happens at the other side of the diaphragm.

Let us again take the diagrammatic representation of the cell—the anode compartment assumed to be filled with salt solution, the cathode compartment with caustic soda solution. We will assume the cation transport ratios for salt 0.35, for caustic 0.20. We shall then have the following pictorial representation of what happens:—

DIAGRAM No. 3.

At the cathode 80 NaOH are decomposed, sending 80 OH towards the anode compartment. In passing through the diaphragm they meet there 65 sodium ions liberated in the neighbourhood of the diaphragm by reason of the 65 chlorine migrating towards the anode, and another 35 sodium ions migrating from the anode towards the diaphragm. Of these 100 sodium ions liberated in the anode compartment, 20 pass through the diaphragm; the other 80 simply form NaOH with the 80 hydroxyls, and that in close proximity to the diaphragm. This caustic is not found in the anode compartment as such, but at once combines with some of the liberated chlorine to form hypochlorite and chlorate, as shown in Table VIII. This again participates in the conveyance of current, and thus matters become more complicated.

Mr. Auer made one experiment in which he attempted to measure all the products of the electrolysis. Into the anode compartment was first placed the concentrated salt solution, allowed to stand therein for 30 minutes, so that the salt solution might penetrate into the diaphragm; then the cathode compartment was filled with caustic soda solution. The results obtained are as follows.

Copper deposited in voltameter .....	3.320 grms.	
Soda obtained as Na <sub>2</sub> O—		Per Cent.
in cathode compartment, Na <sub>2</sub> O = 1.395 grms., or	43.0	
in anode compartment as NaClO 1.540 ..	46.9	
	89.9	
Chlorine obtained—		
as gas .....	1.7128 grms., or	46.2
as hypochlorite .....	1.7395 ..	46.9
Total Cl efficiency .....		93.1
Oxygen gas obtained .....	0.0804 grms., or	1.8

To obtain the soda formed on the anode side of the diaphragm as alkali, and not as hypochlorite, we made a number of experiments with a cell containing three compartments separated by two diaphragms. The anode A was filled with a saturated solution of salt, the centre compartment B with a 4 per cent. solution of sulphate of soda, and the cathode compartment C with a normal caustic soda solution. We employed diaphragms of porous porcelain, and also of nitro-parchment and ordinary parchment. These latter are not good for experiments of this kind; they may contain pinholes, and they easily break. Thus no constant results can be obtained.

The following Table X. gives the results:—

17	60	1.0653	0.100	1.264	94.8	101.2

These experiments do not show the whole of the soda made to be contained in compartments B and C, because some of it is contained in the anode compartment A and in the diaphragms.

We have recorded in the same table some experiments made in the same apparatus with the current reversed. In that case, if a diagram for the migration be made, it will be seen that all the NaHO must be found in the cathode compartments and none in any other compartment. The experiments fully confirm this, and thus furnish another proof that the current efficiency depends chiefly upon the phenomena of migration.

Our experiments show that in a cell which contains pure caustic soda in the cathode compartment a current efficiency

amounting to 0.20 only can be obtained, and that the other 80 per cent. of soda are produced in the anode compartment, near the surface of contact of the two solutions.

If that surface of contact can by any means be brought into the cathode compartment, or nearer to the cathode side of the diaphragm, then some of the 80 per cent. of alkali made in the anode compartment may, by process of diffusion, pass into the cathode compartment, and the current efficiency will increase.

This seems to occur with very low current densities. In the cell of a French inventor, in which only 1 ampère passes per square decimetre of diaphragm surface, the current efficiency varied from 37 to 50 per cent., but the soda solution obtained was very dilute. In such a case ordinary diffusion will bring salt enough to the cathode side of the diaphragm to account for an improved current efficiency.

The cell patented by Hargreaves and Bird effects a material improvement in the efficiency by bringing the cathode in immediate contact with the diaphragm and washing the soda away as fast as it is formed.

We have added a few experiments with an apparatus embodying Hargreaves and Bird's principle of placing the cathode in contact with the diaphragm.

A platinum plate as anode was placed within a porous cylinder, which was filled with concentrated salt solution. The cylinder was closely wrapped with fine wire gauze, serving as cathode, and this was first submerged in a beaker full of cold water, by which means the following results were obtained:—

TABLE XI.

No.	Time.	Cu deposited in Voltameter.	NaOH formed.	Current efficiency.
		Grms.	Grms.	Per Cent.
1	60	1.1575	0.456	31.10
2	60	1.1870	0.698	49.05
3	60	1.2585	0.620	38.85
4	60	1.2375	0.603	38.80

Porous cell, wrapped with wire gauze, placed in cold water.

A very material improvement upon these efficiencies resulted from the employment of a beaker full of hot water (90° C.), as shown in Table XII.

When the cathode was surrounded by steam and washed from time to time with hot water, the results obtained were as shown in Experiment 1 to 3 of Table XIII. In Experiment 4 the cathode was only washed once at the end of the experiment.

Porous cell, wrapped with wire gauze, surrounded by steam.  
\* Washed only once—at the end of the experiment.

In all cases the soda solution contains salt, and is very dilute. It is comparatively easy even for this case to show what strength of caustic solution can be obtained if the current efficiency is to be kept at a given limit. The result of such a calculation has already been published in our Journal.

The results we have now communicated show that, before any satisfactory calculation of the exact value of the current efficiency can be made, much more work must be done in the direction of ascertaining how a current divides between several electrolytes in one solution.

Our results leave no room for doubting that the current efficiency depends chiefly upon the phenomena of migration, or, what is practically the same thing, the conductivity of the solutions; and that, though no accurate calculations can be made at present, a higher limit can always be assigned which in practice is never reached.

Our results show that the phenomena of migration are capable of explaining why the electrolysis of potassium chloride is technically easier than that of sodium chloride; why potassium chlorate is easier to produce than sodium chlorate; why a cell with common salt on both sides of the diaphragms gives better efficiencies than one having pure salt on one side and caustic on the other; and why the production of carbonate of soda is accompanied by a higher current efficiency than the production of caustic soda.

We wish, finally, to thank the Directors of the United Alkali Company, Ltd., for their kind permission to publish our results.

#### DISCUSSION.

Mr. HARRY BAKER said there were several points he was unable to understand, and which Dr. Hurter would doubtless be able to explain at once. In the first place, as to the literature dealing with electro-chemical matters, Dr. Hurter's remark as to some of the most recent works, particularly that of Ahren's, published only last year, was correct, but there was a book which he thought might be brought to the notice of the meeting, "Solutions and Electrolysis," by Mr. W. C. Whetham. That book, only published at the end of 1895, contained a summary of the theories of solution and of electrolysis, and gave many tables of data. At the end of the book there was a long list, some 60 pages of printed matter, of tables of conductivities and migration constants, and references.

In the paper brought before them was a table of the conductivities of ions (Table I.), and he would ask Dr. Hurter if, instead of designating that table "relative conductivities of the various ions," he should not have said that it was a table of the "absolute conductivities." Comparing that with the table of the absolute velocities of the ions which was given in Whetham's book, the significant figures were almost identical, but in the latter they are not given as whole numbers, but are multiplied by  $10^{-5}$ , and then expressed in centimetres per second the velocities of the ions in infinitely dilute solutions under a potential gradient of 1 volt per centimetre at  $18^{\circ}\text{C}$ .

Thus they read in Dr. Hurter's table for the potassium ion a conductivity of 60, in Whetham's, a velocity of 0.00066 cm. per second. The conductivities of those dilute solutions varied considerably with the degree of dilution, and he presumed that Dr. Hurter had taken some convenient average strength of dilution and calculated a table for that. He would like to know what that strength was.

With reference to Table III., dealing with the conductivities, he presumed that the expression "ampères per volt per litre" meant the ampères that would pass from opposite faces of a cube, 1 decimetre in each edge, with a terminal pressure of 1 volt.

Dr. Hurter spoke of an "open cell," and he (Mr. Baker) interpreted that to mean a cell not provided with a diaphragm. Hittorf made use of closed cells, for the reason that if the cells were open, and not closed perfectly tight, and made with inflexible walls, there is generally a bodily transfer of liquid through the porous partition by reason of the electric endosmose.

Referring to the experiments which were described in Table IV., there was one point especially he wished to call attention to, and that was—the various estimations did not agree among themselves with any extraordinary degree of accuracy. Thus, for instance, taking the current efficiency for oxygen, they had under the same conditions 89.30 and 82.20; that was to say the error was nearly 10 per cent. of what they were estimating. It seemed to him that much of the discrepancy arose from the fact that at the electrodes they would have formed layers of liquids of differing composition and specific gravity; and any very trifling matter, as whether an electrode or a partition was exactly upright or horizontal, or slightly tilted over, would make a great deal of difference in the rate at which these layers would mix with the bulk of the electrolyte, and as these layers may exert a profound influence on the progress of the electrolysis, no two experiments would give exactly the same result. As a remedy, he suggested that it would be well to keep the contents of the cells in a state of constant and violent agitation, either by rapidly moving the electrodes, as by small turbines, or by blowing in a current of air, or by circulating the electrolyte. Another method of getting over the difficulty would be to flow quantities of solutions through the electrolytic apparatus towards electrodes or partitions, as the case might be, at such rates that the products were swept away as fast as formed almost, and certainly at a rate greater than the opposite velocities of any of the ions. This might be simply done, and there would be but one disadvantage, *viz.*, large quantities of solution would have to be examined.

In the experiments described in Table VII. a higher efficiency was obtained than was calculable from the transport ratios of the ions, *viz.*, 0.20 to 0.22. It was very easy to obtain an efficiency which was less than theory, but remarkably difficult to obtain an efficiency greater than theory, and there must be some explanation to hand to explain why they should have those large efficiencies. The key to that he thought would be found in an analysis of the caustic soda, for there they would find a noticeable percentage of sodium chloride, the remnant of a still large quantity that had diffused through the diaphragm and by its electrolysis, given a higher efficiency. That remark would apply to a number of the subsequent observations. Thus in experiments made on the principle of the Hargreaves and Bird cell very high efficiencies were obtained, and also in Table X., they had efficiency in the cathode department with a parchment paper diaphragm very variable, but as high as 37 per cent., instead of the theoretical 20 to 22 per cent. In the last case it was specifically mentioned that parchment was very apt to contain pin holes and when Dr. Hurter used porous porcelain the efficiency only varied from 17 to 19 per cent., *i.e.*, just below the theoretical efficiency. It would have been very interesting if tests of the purity of the soda obtained had been given.

There was a point with regard to such experiments as the first few in Table IV. where the cathode is immersed in a limited volume of a solution containing a very small but measured quantity of caustic potash: during the process of the experiment on that weak solution of caustic potash, further amounts of potash are formed, that may be very considerable in comparison with the original amount, and therefore have a considerable disturbing effect on the result of the experiment. Apparently such influences could be traced in the experiments referred to. In many electrical measurements, and in such electrolytic experiments as those named very particular care had to be taken that the test should not alter the thing to be tested, and the remedy here would be to have a constant flow of fresh electrolyte through the apparatus and to aid the removal of the product of electrolysis by agitation of the electrode on the electrolyte.

Attention was drawn to the important remark that "if that surface of contact can by any means be brought into the cathode department, or nearer to the cathode side of the diaphragm, then some of the 80 per cent. of alkali made in the anode compartment may, by process of diffusion, pass into the cathode compartment, and the current efficiency will increase." Dr. Hurter had explained that those pro-

cesses had an efficiency of only 20 per cent. and now here apparently was the loophole through which they could drag the remaining 80 per cent. But if they took into consideration the absolute velocity of the ions, they would be able to calculate readily the speed at which the liquor from the anode compartment must travel through the porous diaphragm into the cathode compartment, and would find that for caustic soda they would be able to get an efficiency of 100 per cent. and pure caustic into the bargain, but only if the cell is fed with lime containing about 1.5 per cent. of salt, and the resultant soda solution is proportionately weak, and that it was impossible to get a strong solution of even approximately pure caustic soda by any means of driving the liquid from the anode compartment into the cathode compartment through the porous partition.

Mr. A. HAY said that with regard to the two curves given on page 101, one of which was theoretical, and the other experimental, it was pretty plain he thought that the great divergence between the two was mainly due to the fact of the counter E.M.F.'s not having been taken into account. That fact would be rather difficult to consider satisfactorily; the counter E.M.F. would depend not merely on the concentration of the solution, but would also depend on the area of the electrodes, so altogether the effect would be a very complicated one. There appeared to be one point common to the two curves; at that point, therefore the results agreed. Higher up, however, there was another point which appeared to be common to the two. Had it been actually obtained by experiment?

Dr. HURTER replied that it was simply put as the beginning and termination of the curves.

Mr. HAY drew attention to another point—he thought a trifling one—in several passages Dr. Hurter spoke of the electrical equivalents due to certain currents passing through the solution. He (Mr. Hay) would like to suggest the term “coulombs” for “ampères” as it would render the terminology somewhat more precise. With regard to the formation of layers of different density, it may be remarked that so long as the layers were arranged in a direction which was parallel to the current, it did not matter, so far as calculation went, whether the liquid was differentiated into such layers or not. But when they had two layers arranged in a direction which was normal to the current as would be the case with a cell having horizontal electrodes, then the conductivity could not be calculated in the simple manner suggested by Dr. Hurter, from the conductivities of the constituents.

Mr. J. B. C. KERSHAW said, with regard to the theoretical aspect of Dr. Hurter's paper, I think it is to be regretted that he has not in any way alluded to the recent correspondence in the columns of “Nature,” upon the vexed question of “Dissociation” and the presence of “free ions” in an electrolyte. Dr. Hurter's paper is based upon the theory of “ionic migrations,” and it is questionable whether this latter theory is so wholly independent of the former as to justify Dr. Hurter in completely ignoring the controversy. If the theory of “free ions” is found to be out of harmony with many facts of chemical change it will have to be relegated to the lumber room for “false theories”; and it is questionable whether the theory of “ionic migration” could then be maintained. Dr. Hurter's experiments, recorded in the present paper, may be urged by himself and others, as supporting the theory, since his calculated and observed current efficiencies agree fairly well.

But in the diagrammatic representation of the experiments with mixed potassium chloride and potassium hydrate solutions recorded in Table IV., there are considerable deviations from the calculated efficiencies; and as Mr. Baker has already pointed out, there are very marked discrepancies in the six last experiments entered in Table IV., each two of which were performed under precisely similar conditions. I do not think, therefore, that Dr. Hurter would care to base his support of the “ionic migration” theory upon experiments, which not only show a marked deviation from the calculated results, but also differ widely, in some cases, amongst themselves.

Turning to the practical aspect of the paper, I wish first to draw Dr. Hurter's attention to the statement that a higher E.M.F. sometimes increases the current efficiency,

and that consequently a better energy efficiency is obtained. Dr. Hurter, in a paper read in 1895, gave the expression  $\frac{aE}{V}$  as representing the energy efficiency for any electrolytic cell. It is evident then, that any increase in  $V$ , occasions loss of energy, and that a very considerable gain in current efficiency is requisite to balance it, if the energy efficiency is even to remain the same, not to speak of a gain.

To take a practical illustration. Say a cell working at 2 volts pressure, shows a 30 per cent. current efficiency. If the voltage is increased only to 6 the current efficiency must spring up to 90 per cent. to maintain merely the same energy efficiency.

It is evident, therefore, that there is quickly a limit to the possibility of a balance in this way, and that the case in which an absolute gain in energy efficiency occurs is almost excluded.

This present paper contains experiments that show a current efficiency of 20 to 40 per cent. is the maximum that may be expected, when electrolysing solutions of sodium chloride, under conditions which may be surmised to obtain in actual manufacturing operations. The inference of course is, that a similar current efficiency, or a lower one, will be obtained in operation on a larger scale, and that the commercial success of such a manufacture will be impossible. This inference is, I believe, wrong.

It is a very common fallacy to suppose that a 90 per cent. current efficiency must be obtained in order to give an electrolytic process the slightest chances of success. Mr. Swinburne, in his recent Cantor Lectures on Commercial Electrolysis, pointed out that this was a mistake, and some recent calculations I have made relating to these processes prove that his views are correct.

I find that power, in most of these estimates of the cost of electrolytic alkali and chlorine compounds, only represents from 30 to 35 per cent. of the total cost, and that even supposing the current efficiency be only half that usually calculated upon, or even as bad as Dr. Hurter's experiments would seem to show, this increase would only bring up the proportion of power cost to between 50 and 60 per cent. of the whole, and there is still a fair margin left, in spite of the increased cost of power, for manufacture at a profit.

Dr. HURTER in replying, referred, first of all, to Mr. Baker's remarks as to how far migration was treated of in text books. The reason for the sentence in his paper was an adverse criticism of a paper he had read before the Liverpool Physical Society. He there referred to the fact that migration was not very well known, and that was his excuse for treating it in an elementary manner. He was perfectly well aware that scientific treatises and scientific men knew all about migration, but he was equally well aware that the ordinary inventor did not know, and that no treatise on practical electrolysis dealt with the subject otherwise than superficially. As regards the application which he had made of the facts of migration, he did not think that they would find any indication of it elsewhere than in the paper he had the honour to bring before them.

With respect to Table I., the numbers there given were not “velocities” but were conductivities, which, when multiplied by  $10^{-8}$ , referred to the conductivity of mercury as unit. It so happened that they appeared to be multiples of the absolute velocities in centimetres per second. These conductivities were referred to infinite dilution of the electrolyte.

With respect to Table III., Mr. Baker had properly interpreted the meaning of conductivity. It gave the conductivity as the number of ampères which would pass, per 1 volt difference of potential, between opposite sides of a cube of 1 decimeter. Similarly he had been properly understood that an open cell meant one in which the current could go from electrode to electrode through the liquid, without having to pass a diaphragm. With reference to the experiments in Table IV., they had always found great difficulty in obtaining absolutely concordant results on repetition. No doubt agitation or circulation of the liquid would assist, but it was difficult to employ these devices, and at the same time insure a correct gas analysis. The experiment was arranged that the electrolysis should

not affect seriously the constitution of the electrolyte by having a large cell with much more than 100 c.c. of liquid in it. Moreover, Mr. Baker would see that it was not the liquid with the smallest amount of KOH which deviated most, but one with 8.41 grms. per litre. Also the three series of experiments *a*, *b*, and *c* were made at very different periods, and after they had learned that a potassium hydrate must be purified by electrolysis. As no effort made so far had brought the results much nearer the theoretical curve, they had given all the results they had in their possession.

The variations in Table VII. to which Mr. Baker referred were no doubt due to salt getting into the cathode compartment. Dr. Hurter had given that as the explanation in his paper to the Physical Society, but since Mr. Auer's experiments bore out Mr. Auer's suggested reason for the discrepancies they had given his arguments due weight.

In reply to Mr. Hay, he quite agreed with his remarks that it was difficult to calculate the electro-motive force of polarisation in such cells, and that was the reason he had omitted that correction in all his calculations as explained in the paper. He had used in a former paper the word "coulombs," but he found that that term was not understood by many readers. As to the calculation of the composition density and velocity of exchange of the layers of solution in contact with the anode and cathode he did not see his way out of that difficulty.

In reply to Mr. Kershaw, any difficulties with respect to the theory of migration or dissociation did not in the least affect his results or the technical value of them. They often used the words "theoretical" and "theory" when they ought to use the words "experimental" and "experience." When they spoke of the theoretical composition of a chemical compound, they really meant the composition as found by such skilled men as Berzelius, Rose, Liebig, Stas, &c. The transport ratios were facts well established, and so were the conductivities. Upon those facts the calculations and experiments of the paper before them were based, and whatever might happen to the theory of migration or dissociation these facts would remain.

As regards energy efficiency, the formulae he had given in the present paper gave some sort of a key to what was difficult to explain, that in some cells a considerable increase in the terminal voltage resulted in a better current efficiency, so that more produce was obtained per horse-power day.

The subject was by no means clear, and he hoped the paper would be a stimulus for more work and thought in the same direction; much more light was still wanted.

## LABORATORY NOTES.

BY W. F. KEATING STOCK.

### *Extraction of Soluble Phosphates from Artificial Fertilisers in the Process of Analysis.*

It is a debateable point whether the treatment of a weighed quantity of any phosphate, which has been acted upon by and still contains free sulphuric acid, with successive small quantities of water, is quite a fair way of extracting the soluble phosphates for analysis. When the phosphate was finely pulverised like superphosphates I have never noticed any appreciable difference in the results whether this was done, or whether the whole quantity of water was added at once, and the extraction made by the method about to be described. But when the phosphates to be examined consisted of vitriolised bones or bone manures containing coarse fragments of even  $\frac{1}{2}$  in. in diameter then the treatment of even 5 grms. by any of the usual methods has failed to give me sufficiently satisfactory results, and I prefer the following method which I have used now for some years:—From 20 to 30 grms. of the fertilizer, carefully mixed and free from adherent lumps, are put into a strong bottle, and from 2 to 3 litres of water, carefully measured, are added at once, and the mixture thoroughly shaken immediately. 20 or 30 ordinary glass marbles are now dropped into the bottle, which is then closed with an india-rubber stopper, and the disintegration is effected by repeated swinging of the bottle to and fro in a horizontal position during two or three hours. The liquid is then allowed to clear by subsidence. An aliquot portion is drawn off, when clear, and the soluble phosphoric acid is determined. If the liquid clears too slowly it may be filtered through a double dry filter, rejecting the first 50 c.c. or so.

### *Improved Copper Zinc Couple for the Determination of Nitric Nitrogen in Water Analysis.*

A 7-oz. wide-mouthed stoppered bottle is filled nearly to the neck with granulated zinc. Water is added, then a few drops of 1 to 3 of sulphuric acid and 10 c.c. of 3 per cent. solution of copper sulphate. The stopper is inserted, and the bottle is vigorously shaken for one minute, during which time the stopper is held by a finger, and the operation is performed over the sink. The stopper is now removed, and the mouth of the bottle is covered with a piece of soft copper gauze. The couple is then thoroughly washed at the tap and drained. 100 c.c. of the water to be analysed are placed in the bottle: the stopper is securely inserted and the arrangement is allowed to stand at rest at a temperature of from 20 to 25° C. for 48 hours. The test is completed by thoroughly shaking the bottle, drawing off 50 c.c. of the water, adding this to 200 c.c. of ammonia free water in a retort or flask, running in 5 c.c. saturated sodium carbonate, distilling and nesslerising as usual. This process has been found correct between the limits of 0.0863 and 4.181 grains of nitric nitrogen per gallon, when pure potassium nitrate was used in solution in ammonia-free distilled water. The couple when washed and recoppered is again ready for use. These couples will last for many months, and their convenience will be obvious to anyone who has had to clean and prepare 20 or 30 slips of zinc foil at one operation. It will be well to add that all new stoppered bottles intended for this purpose should have their stoppers carefully reground into the necks with a little fine emery and dilute sulphuric acid. And I may also say that dilute sulphuric acid is an excellent agent to employ with emery for grinding glass, being far superior to turpentine or anything else I have tried (see Chem. Soc. Jour. 1881, Trans. 100).

### *A New Extraction Apparatus in which the Solvent acts at Boiling Point.*

The apparatus exhibited has been in use in my laboratory for three or four years. It consists of (1) a boiling flask

of 150 c.c. capacity. (2) a glass tube which acts simultaneously as a bye-pass for the vapours of the solvent and a support for (3), another tube which contains the substance to be extracted. The bye-pass tube is 12 cm. long and 2.5 cm. internal diameter. It is shaped like a test-tube. At the bottom it has a circular aperture of 5 mm. diameter, and at one side, 4 cm. from the bottom, another circular aperture of 7 mm. diameter. It is fitted to the neck of the flask by means of a sound cork. The substance to be exhausted is contained in another tube, which slides easily into the bye-pass tube, and it is provided with a short stem which protrudes through the aperture at the bottom of the bye-pass tube. The sample rests upon a filter made by putting a plug of cotton-wool into the short stem of the containing tube, and then pouring a little filter paper pulp on to this, after which alcohol and ether are passed through to free the filter from water and extractive matter. The top of the bye-pass tube is connected to an upright condenser by means of a good cork, and the boiling-flask is heated either by water-bath or sand-bath. I prefer the latter even with ether as the solvent. The apparatus before you will exhaust 10 grms. of cotton cake and uses only 50 c.c. of solvent.

#### *Apparatus for ascertaining the Softening Point of Coal Tar Pitch.*

This apparatus consists of a copper vessel A, of cylindrical form, 13 cm. high and 12 cm. wide. It is fitted with three little copper brackets fixed inside the vessel 1 cm. from the top, and three similar brackets 7 cm. from the top. These brackets are arranged at equidistant points around the circumference of the vessel, the lower three being fixed so as to lie in the intervals between the upper three. The object of these brackets is to carry a circular perforated zinc platform, B, fitting easily into the copper vessel. This has three semi-circular gaps cut out of its circumference corresponding in position to the brackets above mentioned. This zinc platform has an aperture in the centre 1 cm. in diameter, and round this is soldered a perforated zinc tube 5 cm. high. At opposite sides of this tube are soldered two stoutish brass wires 14 cm. long, and these carry a little copper disc having a 5 mm. hole bored through it centrally. This fitting acts as support for the necessary thermometer, which is fixed in the perforated tube by means of an ordinary cork. The thermometer is set so that the zinc platform is just midway of the bulb. The use of the apparatus is to obviate the necessity for strings or wires to support the test pieces of pitch. The copper vessel is filled with water at the required temperature. It is set on an iron plate over a suitable burner. The zinc platform is lowered on to the bottom set of brackets, and left there till the temperature is steady. It is then raised, and a half revolution allows it to rest on the upper brackets. The test pieces are then laid upon it, four at a time. It is reversed a half turn, and lowered again. It now rests upon the lower brackets, and the test commences. At the end of the time agreed upon by the contract note, the platform is raised, a half turn is given, and it rests upon the upper brackets. The test pieces are then twisted one after the other without loss of time. The thermometer acts as a handle by which to raise, lower, and turn the platform. The gain in time and uniformity of results is very great when this apparatus is used as compared with tying or wiring of the test strips.

#### INDIGOTIN AND NITROBENZOL.

BY DR. R. W. GERLAND.

An examination of the behaviour of indigotin with nitrobenzol has become necessary in the interests of the method for the determination of indigotin described by me in this Journal, 1896, 16. The preparation of pure nitrobenzol causes great difficulties, while the commercial article is of a high degree of purity but still contains a small amount of brown tarry matter, which is only partially left behind by repeated distillations and blowing-over with steam. Sulphuric acid acts more energetically upon the impurity than upon the nitrobenzol, but even an acid reduced to 30 per cent. gives unpleasant results: the nitro-

benzol separates badly, and when distilled or blown over by steam, has a deep yellow colour after washing with caustic soda. Trials with mild reducing agents or with permanganate or chromic acid in acid or alkaline solutions proved equally unsatisfactory. The best results I obtained by repeated crystallisation. The nitrobenzol thus purified has a very pale colour and freezing point of 7° (thermometer certified by the Berlin Reichsanstalt). These impurities may be products of decomposition of the nitrobenzol; they do not affect the results of indigo tests unless the quantity of the indigotin fall as low as a few decimilligrammes.

Nitrobenzol dissolves indigotin very slowly in the cold. On warming the action takes place readily, the solution is pure blue and soon becomes of great depth. With the temperature rising to about 65° red becomes mixed with blue, and at about 95° the solution is pure blood red, and this increases in brilliancy with the further rise of temperature. The cooling solution does not change back to blue at once; the red remains for hours and if cooled to about 2° pale blue crystals appear in the red liquid, which at from 1 to 2° turns blue again. Contact with a fresh glass surface immediately effects the change from red to blue; a pipette for instance dipped in the cooled red solution can only be charged with a blue solution. Weak solutions on the other hand do not alter their blue colour on heating.

It is difficult to ascertain the solubility of indigotin in nitrobenzol at the boiling point. The figures obtained vary from 0.5 to 1 gm. in 100 c.c. With the experience recently gained I hope to succeed better. The solution has a remarkable tendency to supersaturation, which is the more persistent the less the excess of indigotin it contains. It may require days, weeks, and even months before the normal condition is reached, and weeks even with a small amount of crystals present. This peculiarity has to be taken into consideration in accurate estimations of indigotin, the more so, the smaller its proportion to nitrobenzol, and should be counteracted by long standing with frequent shaking. In ordinary indigo testing abundance of indigotin crystals are present which expedite the separation, so that after a few hours' standing nearly all the indigotin has separated. Still the quantity remaining in solution may be three or four times that which would be left after some days.

Attempts to estimate the indigotin left in solution in nitrobenzol in the cold by chemical methods were not successful. From 25 c.c. of such a solution (the quantity I usually employ), evaporated on the water-bath, a residue weighing 0.0021 gm. was obtained; another solution gave the same result. These residues were of a dirty colour and with careful manipulation only would give the indigo reaction. In several trials the nitrobenzol was blown over by steam, care being taken to remove the last trace, but the residue was more contaminated, and I despaired of arriving at approximate results even by the sulphonic acid described (*loc. cit.*). Presence of hydrochloric acid whilst steaming did not improve matters. But colorimetrically the estimation is easily done with every appearance of reliability, if the tendency to form supersaturated solutions be taken advantage of.

0.0090 gm. indigotin were heated with 50 c.c. nitrobenzol; directly after cooling, before the red had changed to blue and crystals had separated, measured quantities were added to nitrobenzol until the shades were matched.

1 c.c. of the solution in 45 c.c. nitrobenzol was equal to the normal solution.

1 c.c. in 20 c.c. nitrobenzol was equal to the solution of indigotin crystals two hours after cooling.

Therefore—

	Grm. Indigotin.
25 c.c. of the normal solution contain .....	0.0001
25 c.c. of the lead supersaturated solution contain..	0.000225

The total neglect of the amount of indigotin left in the solvent would accordingly have no appreciable effect upon the results of an indigo test.

I have taken all the more interest in these estimations as my colleagues, who had adopted this method, arrived indirectly at figures of incredible height, neglect of which would vitiate the results.

My former recommendation of a saturated solution of indigotin in nitrobenzol for indigo testing may, therefore, stand, and the loss of solvent during the operation, amounting to from 2 to 5 c.c., need not be made good; it will compensate the larger amount of colour left in the supersaturated solution.

The nitrobenzol solution is rapidly bleached when exposed to light but it keeps indefinitely in the dark.

#### Testing Indigos.

The apparatus I described has rendered good service and has not been altered, except by the glass tube, which acts as condenser and connects the test tube of boiling nitrobenzol with the aspirator, being replaced by a brass one, which has the advantage of not breaking off and thereby endangering the trial when drops of water fall inside.

The operation should be started with well dried apparatus and materials, the crystals of indigotin collected on a small filter, extracted with acid and alcohol, dried and weighed, washed with benzol, digested with strong hydrochloric acid, and boiled with addition of water, then boiled with solution of sodium carbonate, washed, dried, and weighed. Subsequent washing with cold alcohol decreases the weight by about 0.1 for 100 indigotin. The latter still contains ash to about 0.1 per cent., which I suspect to be derived from the glass vessels. With careful working concordant results are obtained, and even with spurious indigos the true amount of indigo is found. Thus "refined indigo of 98 per cent." yielded: moisture 1.30, nitrobenzol extract 74 per cent., but in the same only 24.31 per cent. indigotin.

My expectation that the results by this method would be lower than those by the permanganate one, especially for poor indigos, has not been borne out by experience. The results are sometimes higher and sometimes lower without any regularity.

#### Estimation of Indigotin on Dyed Cotton and Wool.

The method has served excellently for the determination of indigotin on dyed goods, but it has to be adapted to the purpose. Indigo-dyed cotton in the vapours of boiling nitrobenzol rapidly loses the greater part of its indigotin and becomes dirty white, but no amount of boiling will make it quite white. Exposure to air again turns the cotton blue and nitrobenzol will again extract some indigo, but with numerous repetitions I succeeded in removing only about  $\frac{1}{3}$  of the total amount. Then it takes weeks for the colour to develop. But if the cotton be treated with boiling acetic acid, complete extraction rapidly takes place and the cotton becomes pure white. It is, however, preferable for the estimation of indigotin to destroy the fibre (both wool and cotton) by treatment with acid, and extract the residue after filtering, washing, and drying, with nitrobenzol. The results of parallel tests show an agreement, not surpassed by inorganic analysis.

Respecting the second method of estimating indigotin, by titration of the sulphonic acid with hydrosulphite according to Müller-Bernthsen, I have collected some experience. I have also investigated the indigotin-sulphonic acid, and shall have much pleasure in communicating the results on a future occasion.

#### DISCUSSION.

Dr. GROSSMANN said that the fact of a number of tests agreeing to a second decimal was not, in his opinion, a proof that the method must be, under all circumstances, correct. In all cases of indigo, samples of different strengths should be prepared by mixing chemically pure indigotin with red, brown, glens, and ash substances in different proportions, and these different mixtures should be used for checking the accuracy of the method.

Dr. GERTAND perfectly agreed with Dr. Grossmann respecting the proof of the correctness of a new analytical method. In this case he had measured the indigo against ammoniacal copper solution, by means of hydrosulphite, according to Miller's method. He had, further, in order to test the fact of impurities, worked with weighed quantities of indigotin and natural indigos, and found the results agree with the calculated quantities, and he thought

this was sufficient proof for any chemist. In reply to Dr. Knecht, he thought the method of nitrobenzol adapted itself well to the exact estimation of indigotin on cotton, wool, or any other fibre; but he preferred to destroy the fibre by treatment with weak sulphuric acid; then, after washing and drying the residue, to treat it with nitrobenzol, and extract pure indigotin, as mentioned in the paper. He had found that in three parallel analyses the difference in results amounted to 1 in 300—a result quite as good as they might expect in any mineral analysis.

#### THE FIXATION OF PIGMENTS WITH ALBUMIN.

BY R. J. FLINTOFF.

LAST session I read a paper before this Society, entitled "The Functions of Albumin as a Fixing Agent for Pigments on Cotton," and drew attention to the fact that the addition of albumin to a printing colour increases its intensity of shade. The explanation of this phenomenon as stated in the paper was that the albumin increased the opacity of the layer of colour, and also, while in solution, distributed the printed pigment over the fibre with a more even and solid surface. The result is that the actual quantity of light rays reflected is increased by both these conditions; because in the former case less rays are transmitted, and, in the latter, less are scattered.

I have now done further work on this subject with a view to discover which of the above causes plays the most important part in bringing about "intensification."

The method of investigation consisted in producing on the fibre two layers of colour, each presenting a perfectly solid and smooth surface, that is, with one of the above conditions common to both. To the one an addition of albumin had been made, and in every other particular they were similar. It is, therefore, obvious that any difference in shade between these two colours, due to the albumin, must be attributed to an increase in the opacity of the colour on the fibre.

To produce a pigment on the fibre possessing these required properties, it is necessary to print the constituting parts on the cloth in a state of solution or else so finely divided that it almost approximates to solution, and to bring about their combination afterwards. Then a pigment colour will have been produced on the cotton fabric having the desired reflecting surface. Accordingly the following mixtures were made:—

- 1.—150 grms. alizarine, 20 per cent. (blue shade).  
96 c.c. acetate of lime, 16° Tw.  
90 c.c. sulphocyanide of alumina, 32° Tw.  
84 c.c. exalate of tin, 25° Tw.  
580 grms. starch thickening.
- 2.—100 grms. alizarine, 20 per cent. (blue shade).  
46 c.c. acetate of lime, 16° Tw.  
50 c.c. acetic acid, 9° Tw., 30 per cent.  
90 c.c. acetate of chrome, 32° Tw.  
720 grms. starch thickening.
- 3.—50 grms. alizarine, 20 per cent. (blue shade).  
250 c.c. acetic acid, 9° Tw., 30 per cent.  
75 c.c. acetate of lime, 16° Tw.  
25 acetate of iron, 23° Tw.  
600 grms. gum thickening.

Each of these mixtures was then divided into two equal parts. To the one an aqueous solution of albumin was added, and to the other a corresponding volume of thin starch paste. The two printing pastes made from each of the above mixtures were then printed on the same fent from the same roller and dried. After drying, the colour containing the albumin was darker in each case. For instance, in No. 1 mixture, the albumin was an orange colour, and the other was lighter in shade. The difference in shade between the comparable portions of each mixture was judged to be about the same.

The fents were now steamed 1 hour and 20 minutes without pressure, and during this process the pigments were precipitated on the fibre, being respectively coloured red, chocolate, and lilac. In my previous experiments the pigments were precipitated before printing, whilst now they have been precipitated on the fibre for the purpose previously explained. On comparing the two parts of each

fect, there appeared very little difference in shade between them; but the one containing the albumin was slightly darker. Now, since the only difference between these two series of shades is that those containing the albumin have increased opacities, and as their intensities exhibit only slight differences, the deduction must be made in these cases that the decreased transparencies of the layers of colour have not produced corresponding increased intensities in the shades of the colour-lakes. Further trials were made similar to the above, only the colouring matters and mordants were varied and gave in every case corroborative results.

One interesting fact noticed was the addition of albumin to the printing colour increased the fastness to light of the resulting shade. This, I presume, may be attributed to the coagulated albumin surrounding the particles of pigment and protecting them from the direct action of the light. Similar experiments could not be made with basic colouring matters, in so far as albumin precipitates the tannic acid and prevents its complete combination with the colouring matter.

I may here mention, incidentally, that the precipitate formed when aqueous solutions of albumin and tannic acid are mixed together, does possess to some extent the power of combining with certain colouring matters. If, for instance, albumin solution be added to the printing paste of a basic colouring matter, a slight thickening of the mixture is noticed, owing to precipitation, and the colour is very materially altered in shade. This may then be printed upon cotton, and after steaming it is found of an entirely different shade from the one produced with tannic acid alone. Moreover, it is apparently quite as fast to soap as the antimony-tannate lake of the same colouring matter. It may be shown that this substance possesses dyeing properties in a totally different and more direct manner. Aqueous solutions of tannic acid and albumin are mixed together in the cold and the precipitated substance washed by decantation with cold water, and finally filtered. If this compound is then suspended in the aqueous solution of a basic colouring matter, it becomes dyed and may be washed without losing its colour. After drying and grinding, it has the appearance of a bright highly coloured powder. This method may possibly be useful for the preparation of pigments for special purposes.

I fear these remarks are a little irrelevant to the general tenour of this paper; but I have inserted them because they have an indirect relationship to the subject, since they were suggested from the results of experiments performed during the investigation.

From the facts so far obtained one would naturally conclude that the cause of the phenomenon of intensification is the reflection of an increased number of rays of light, owing to an improved reflecting surface, which results almost entirely from the more regular distribution of the pigment over the surface of the cotton fabric. But there is one important possibility which has not yet been taken into consideration in this argument, and supposing it to exist one might very easily prove the conclusions arrived at not altogether reliable. All the pigments precipitated on the fibre were very dark shades and hence the opacity of a film of such colour is very much greater than a film of so small a quantity of coagulated albumin as exists in the colour.

The point I wish to emphasise must be fairly obvious. That so long as the opacity of the actual layer of colour is great as compared with the opaqueness of the coagulated albumin contained in the colour, so long will the latter be a very small factor in the phenomenon of intensification. But should the former become less and less, whilst the ratio of the latter to the whole opacity increases—although the actual quantity of albumin remains a constant—then the opacity due to the albumin will become a proportionately greater cause in the phenomenon. And it is possible to conceive a certain adjustment between pigment and albumin, when the opacity of the former would be infinitesimal as compared with the latter; and should "intensification" be still observed, the former generalisations could hardly be true.

Now, since in the experiments previously described very little light is transmitted through the layer of colour itself, a

still further slight decrease in the quantity of transmitted light would not materially affect the intensity of the colour; but if any alteration could be perceived, it would be a very slight increase in the depth of shade. This has actually been observed, and, therefore, in order to note the effect of precipitating on the cotton fabric more transparent films of colour, a further series of experiments were made. With this object in view the mixtures previously prepared were considerably reduced with starch paste, and these were then printed exactly under the same conditions as the dark shades. These shades being very much lighter were consequently more transparent; but the differences in intensities between the albumin pigments and the other ones were practically just the same as with the darker colours.

From the results of these experiments I have arrived at the conclusion, that the increase in the intensity of the colour of pigments fixed with albumin is almost entirely due to the property possessed by albumin solution of spreading the pigment over the surface of the cotton fabric with a more even face, and, hence, with an improved reflecting surface. With regard to the coagulated albumin increasing the opacity of the layer of colour and, consequently, resulting in an increase in the intensity of shade, I have found this to be always a constant quantity, regardless of the strength of the colour, and, further, only a very small causal factor in the phenomenon.

MR. F. J. R. CARULLA IN THE CHAIR.

## THE COMMERCIAL POSITION OF SULPHATE OF AMMONIA.

BY F. J. R. CARULLA.

(This Journal, 1896, 863.)

### DISCUSSION.

THE CHAIRMAN congratulated the section on the fact that they were holding their first meeting at Burton-on-Trent. A desire had been expressed, after the reading of his address, that on some convenient occasion a discussion should follow. That such a course might do good was obvious from the discussion that took place at a meeting of the Manchester Institution of Gas Engineers, following a paper by Mr. T. N. Ritson, three days after the delivery of the address, and which by a curious coincidence, but quite independently, went over much of the same ground as the address, a proof, if one were needed, of the acute character of the situation as it was in November last, but which had since improved, although the anomaly that they desired to remove still remained. It would seem useless, however, to look for relief to suggestions for the better employment of ammoniacal liquor in the manufacture of

some other product than sulphate, for, if followed, those interested might be placed in the position of the fruit-growers of the south of England, who, following Mr. Gladstone's advice, turned their harvest into jam, spending large sums in plant for the purpose. So many went into the new industry as to cause a plethora, thus placing them in a worse plight than they were before. And yet no sensible man would say that Mr. Gladstone's advice was not good. The obvious requirement in the case of sulphate of ammonia was to bring the farmer to see where his true interest lay, and in this sense Mr. Ritson's paper and the discussion which appeared in the *Journal of Gas Lighting* for December 1 and 8, 1896, would repay perusal. A noteworthy point in the discussion by the gas engineers was the fact how some of the largest buyers of sulphate of ammonia, namely, the manufacturers of artificial manures, were overlooked. Almost every speaker who referred to the farmer, including the author of the paper, recommended that he should be taught how to compound artificial manures for himself, thus turning every farm into a small manufactory. That this might be the right thing to do in particular instances one could quite believe, but it was not easy to see how the abolition of the large customer, and his replacement by a number of small ones, was going to mend matters.

Mr. Ritson said, with great discernment, "There is no doubt that sulphate of ammonia is the nitrogen *par excellence* for compounded artificial manures. It can be mixed and stored. . . . Mixed manures prepared with nitrate of soda cannot, however, be stored for any length of time, from the fact that it deteriorates and deliquesces." This property of sulphate, which ought to be impressed on the farmer, would evidently recommend it with still greater force to the artificial manure manufacturer, who might be left with heavy stocks at the end of a season.

What seemed of importance was that the farmer should understand the value of nitrogen as such in any manure, no matter the form in which it might be present. The Fertilisers and Feeding Stuffs Act, passed recently for the protection of the farmers, rightly took no cognisance of the form in which the nitrogen appeared, the unit, no matter whence derived, being given the same value. Such legislation would appear to be a powerful tool, which, properly handled, should help to bring about the proper appreciation of the nitrogen in sulphate of ammonia.

It was not likely that there was any intention on the part of the gas engineers to injure the artificial manure makers, and as probably none of the latter were present, the discussion became rather one-sided. For this reason it was all the more desirable that the matter should be ventilated before a meeting in which all the various interests were represented.

Mr. J. O'SULLIVAN said that the authorities he had consulted concurred on the equal value of the unit of nitrogen, whether derived from nitrate of soda or from sulphate of ammonia, and he thought, consequently, that farmer was the wisest who availed himself of the variations in prices, and always bought the manure which, nitrogen for nitrogen, was the cheapest. He would ask whether any experiments had been made, such as those of Lawes and Gilbert, to prove the equal value of the unit of nitrogen in nitrate of soda and in sulphate of ammonia for the purposes of the agriculturist.

Dr. F. CLOWES referred to the enormous expenditure incurred by the Scottish Ironmasters in adding ammonia absorbing plant to their blast furnaces. He knew that the owners of some English blast furnaces had followed suit and that there were others who were also about to put down plant for this purpose. If the use of sulphate of ammonia was decreasing he failed to see what benefit could be expected to result from this large expenditure.

Mr. JOHN WHITE said that what he felt to be a grievance was that wherever nitrate of soda supplanted sulphate of ammonia they were losing the benefit of a home manufactory. In regard to the Fertilisers and Feeding Stuffs Act, to which reference had been made by the chairman, it was quite true that the unit of nitrogen was given the same

value in it no matter whence derived. Although going away a little from the subject he would add that the Act was practically inoperative owing to the manner in which it prescribed that the sample should be taken. What was wanted was the appointment of inspectors as had been done under the Food and Drugs Act.

Mr. J. O'SULLIVAN said it struck him that the great obstacle to the spread of the use of sulphate of ammonia was its name. The name "nitrate" carried at once the idea of nitrogen to the ordinary man's mind, whereas "sulphate" did not. If sulphate of ammonia could be rechristened so that the name should convey this idea it might be a good thing.

The CHAIRMAN, in reply, said that experiments had actually been conducted over and over again in the sense indicated by Mr. O'Sullivan, with the result that the unit of nitrogen was found to be of equal value in the two manures, or practically so. Of course failures might occur with sulphate of ammonia if ignorantly used and brought into contact with lime, when loss of ammonia must of necessity occur. He would have a caution printed on every page of all sulphate literature to prevent the occurrence of this. In regard to the question of English ironmasters having followed the Scottish ones, it should be remembered that in Scotland almost all the furnaces were worked with raw coal, whereas the English practice was to use coke. In this case the ammonia could only be recovered at the coke ovens. The English firms who were putting down absorbing plant, doubtless would also use raw coal and they might have made their arrangements before the commencement of the present depression. As far, however, was also recovered and this product was valuable, the action of the ironmasters might turn out profitable after all.

Dr. CLOWES thought it was desirable to point out that the reference to lime made by the chairman was to caustic lime, as most soils contained lime in combination.

The CHAIRMAN said this was so, it was of course only in the case of bringing lime in an uncombined form or only hydrated into contact with sulphate of ammonia that loss occurred.

## ON KJELDHAL'S PROCESS.

BY JAMES O'SULLIVAN, F.I.C., F.C.S.

At the time this process for the estimation of organic nitrogen was published I had considerable experience (this *Journal*, 1892, 327) with Dumas', and knowing the time and trouble entailed by the latter I wished to adopt the former, which would take less time. I inquired if it had been employed to determine the nitrogen in bodies similar to those I had to deal with, and I found it had, yet no one had proved its results in this direction, by checking them with those obtained from the same bodies with Dumas' method. A few determinations were made with this object in view, and I came to the conclusion, as the results will show, that Kjeldahl's process gives the same results as Dumas'.

Re-agents used. A 40 per cent. solution of sodium hydrate to which 2 to 3 grms. of potassium sulphide per 100 c.c. were added, this solution was boiled for some time.

A mixture of 1 part of strong sulphuric acid and 2 parts of Nordhausen sulphuric acid.

A solution of sulphuric acid containing 0.008 gm. of sulphuric anhydride per c.c.

Powdered potassium permanganate.

A blank experiment with these re-agents gave no ammonia.

It is not necessary for me to go into details as to the preparation of a solution for a determination of its nitrogen, or to describe the manipulation of either of the processes as these are already well known; I wish, however, to mention that at the suggestion of Dr. Harrow, about 0.5 gm. of mercuric oxide was added with the mixture of sulphuric acids in the Kjeldahl's oxidation process. This oxide hastens the oxidation and the potassium sulphide in the sodium hydrate when added in excess, before distillation, dissolves the sulphide of mercury first formed.

The following are the results obtained by these processes, and are expressed in percentage of albuminoids on total solids in nitrogen ( $\times 6.25 =$  albuminoids):—

- (1.) Malt extract (mash extract), Kjeldahl's 3.8, Damas' 3.78
- (2.) Ale, Kjeldahl's 3.5, Damas' 3.22.
- (3.) Ale, Kjeldahl's 4.15, Damas' 4.31.

By employing the sulphuric acid of the strength mentioned for receiving the ammonia in the distillation the number of c.c. neutralised multiplied by 0.0028 give nitrogen, and by 0.0175 give albuminoids.

#### DISCUSSION.

Dr. CLOWES remarked that the Kjeldahl process was now in very general use for estimating nitrogen in organic substances. In his own laboratory the substance was simply heated with the strong acid and potassium sulphate until the liquid became clear. The cool liquid was then transferred to a larger flask, and a solution of sodium hydrate, containing more than enough alkali to neutralise the acid, was poured into the flask in such a way as to form a separate layer. Steam from a separate vessel was then blown through these layers of liquid. Heat was produced by the mixture of the acid with the alkali, and the current of steam carried over the ammonia through a condenser into the standard acid. This procedure was convenient, and was rapidly carried out.

#### A NOTE ON MALTOSE.

BY JAMES O'SULLIVAN, F.R.C.S., F.R.S.

THE numerous papers on the hydrolysis of starch which have appeared since C. O'Sullivan's first paper on this subject (Chem. Soc. Journ., 1872) leave little to be desired. I must, however, agree with Dr. Armstrong (Proc. Chem. Soc., p. 244), "that we should no longer be content merely to determine certain analytical factors; we ought rather to seek for chemical methods which would render it possible to separate and isolate the products." Maltose was separated by C. O'Sullivan from the transformation products of starch, obtained by the action of the cold extract of malt, and its properties described. He gave the  $[\alpha]$ , 154—155, and its cupric reducing power between 62—63, and Brown and Heron 61.0 (Chem. Soc. Journ., 1879).

It occurred to me to determine the properties of maltose prepared by transforming starch with precipitated diastase—diastase precipitated from malt extract by alcohol—thus insuring the absence of the crystallisable sugars contained in malt extract from the maltose. Maltose prepared in this manner and crystallised from water gave an  $[\alpha]$ , 154, and this preparation crystallised from alcohol gave  $[\alpha]$ , 154.5 K = 62.7. The latter was again crystallised from alcohol and gave the following results:—

- (I.) C = 4.164 D = 3.96  $[\alpha]_D^{20}$  155.0
- (II.) C = 1.558 D = 4.00  $[\alpha]_D^{20}$  155.3.

Determinations of the cupric oxide reducing power were made by employing weighed quantities of the maltose, and the following are the results in a tabulated form:—

Experiment.	Grams. of Maltose taken.	Cupric Oxide weighed.	Grams. of Maltose to reduce 1 gm. of CuO.
I.	0.1070	0.1190	0.7181
II.	0.1180	0.1645	0.7173
III.	0.1065	0.1465	0.7269
IV.	0.1170	0.1610	0.7134
V.	0.1175	0.1630	0.7208
VI.	0.1200	0.1660	0.7228

The average quantity of maltose, from these results, required to reduce 1 gm. of CuO is 0.7138 gm. or a K of 63 taking dextrose at 100. If this number be employed in calculating from the CuO obtained in the above determinations, the quantities of maltose found come out as near

as one could wish with the amounts of maltose taken as the following columns show:—

Experiment.	Grams. Maltose taken.	Maltose found.
I.	0.1070	0.1072
II.	0.1180	0.1184
III.	0.1065	0.1050
IV.	0.1170	0.1180
V.	0.1175	0.1173
VI.	0.1200	0.1195

The maltose was first dried in vacuum over sulphuric acid, then in a current of dry air at 100°, and finally in a current of dry air at 100° under a pressure of 100—150 mm.

In determining the cupric oxide reducing power I have in no way deviated from C. O. Sullivan's method (Chem. Soc. Journ., 1876, 2, 130). I find, however, that the weight of the ash of a filter is doubled by filtering the copper solution through it, as in the determination of the reducing power, and that this is not due to any precipitation of the solution but is due to a combination of the copper with the cellulose of the filter.

25 c.c. of Fehling's solution, diluted with 25 c.c. of water were boiled, as in the determination of a reducing power, for 12 minutes, it was then passed through a filter, (1) the filtrate from this was immediately passed through another filter, (2) and the filtrate from this through another filter, (3) about 400 c.c. of boiling water were used in washing the solution out of each of these filters. The ashes of the three filters weighed 0.0025, 0.0025, and 0.0023 grms. respectively, whilst the ash of the filter weighed only 0.001 gm. The ash of each of the filters was dissolved in a drop of dilute hydrochloric acid, and upon testing with potassium ferrocyanide showed the presence of copper.

The numbers given in the above determinations of cupric oxide reducing powers were obtained by employing different copper solutions so far as "age" was concerned; some were determined with Fehling solution which had been made up 13 months, and others with a solution which was only made three days, and I fail to see any practical difference in the results obtained. Two determinations of the K of a sample of large crystallised dextrose prepared from cane sugar by invertase—not yeast or yeast extract—and dried as this maltose was, gave with one of the copper solutions a K 101.4 and 102.4, and the last number is the highest I have ever obtained for a sample of dextrose from cane sugar. I must say, from my experience, that the K of dextrose almost invariably comes out 1—2 per cent. above 100, whilst that of invert sugar comes out as much below.

#### DISCUSSION.

Dr. A. L. STERN pointed out that Mr. J. O'Sullivan, in calculating a mean value of the K of maltose from his experiments on one sample of maltose, and employing the mean value to calculate (in each of the same experiments), the amount of matter equivalent to the copper oxide weighed, and comparing this with the amount of maltose taken, had adopted a method which was bound to give apparently good results whether his original specimen of maltose was pure or not.

He also expressed surprise that Mr. J. O'Sullivan still found such low numbers of the K of dextrose, as Mr. C. O'Sullivan, F.R.S. and himself had recently published a paper in the Journal of the Chemical Society describing a large number of experiments, which had led them to the conclusion that the old value was materially low, and which was confirmed by other workers.

MR. THOS. FAIRLEY IN THE CHAIR.

### THE QUALITATIVE SEPARATION OF ARSENIC, ANTIMONY, AND TIN.

BY S. G. RAWSON, D.S.C., F.I.C.

Lecturer in Chemistry, Technical College, Huddersfield.

To any originality in the process which I propose describing I can lay no claim, the principles involved depending upon a combination of certain well-known methods. The suggested separation of these metals is based primarily upon the use of oxalic acid as originally published by Clarke in his paper, *Chem. News*, 21, 124, upon the quantitative estimation of these metals, a process which to me never seems to have come into the prominence which it so thoroughly deserves. I have but little faith in the methods now employed, especially in those for the separation of antimony and tin. The former metal is frequently evolved either as the hydride or deposited as a black stain upon platinum; the tin being thrown down upon zinc, this deposit is then scraped off, dissolved in acid, and the solution treated with mercuric chloride. That other people share in my disbelief in this method is shown by the fact that in so far as my knowledge goes, I have never heard in any examination of more than two of those bodies being given for qualitative determination in one and the same substance. Even under these favourable conditions, it is seldom that the mixture contains only a small percentage of one of the constituents; the amounts more usually approximate to equality, the difficulties of separation being thereby much reduced. The method I would suggest is as follows:—The sulphides of the metals are washed upon the filter paper, and the whole or part of the residue is placed in a test tube and boiled with 2 or 3 c.c. of concentrated hydrochloric acid, to which a drop or two of nitric acid is added, and again boiled. A yellow residue after the treatment with hydrochloric acid gives a preliminary clue as to the presence of arsenic, this sulphide being slightly, if at all, attacked by the acid. A saturated solution of oxalic acid is added in quantity sufficient to fill two-thirds of the test tube, the whole is boiled and crystals of oxalic acid are added until a hot concentrated solution of oxalic acid is obtained. A stream of sulphuretted hydrogen is passed, the whole of the arsenic and antimony being precipitated as sulphides, which are filtered off, the tin remaining in solution. To the filtrate ammonia is added until distinctly alkaline. If a precipitate should then appear, which will not be the case unless a large amount of tin be present, add ammonium sulphide drop by drop until the precipitate redissolves, this it will do very readily. Acidulate with acetic acid, a heavy white precipitate, turning brown, indicates tin as a mixture of oxide and sulphide. It may be here noted that the treatment of ordinary ammonium sulphide with acetic acid produces a precipitate of sulphur, but the appearance of the precipitates formed in the two cases is quite distinct and

cannot be mistaken. Turning again to the residual sulphides of arsenic and antimony, these may be treated either with ammonium carbonate in the well-known way or, and preferably I think, as follows:—Dissolve in hydrochloric acid with two or three drops of nitric acid, boil and place the solution in a Marsh apparatus. The evolved hydrides are then passed through a solution of silver nitrate, and the antimonide of silver formed filtered off. To the filtrate add a few drops of silver nitrate, and then very cautiously ammonium hydrate until the yellow precipitate of silver arsenite appears. The silver antimonide precipitate is washed, boiled with tartaric acid and filtered, a little hydrochloric acid is added and sulphuretted hydrogen passed through the filtrate, orange red antimony sulphide being thrown down. To both of these precipitates the ordinary reduction and sublimation tests can be applied. The above method gives thoroughly good results and with amounts of the respective sulphides varying within wide limits, and does not require that tinkering with bits of platinum foil and of zinc which is both unreliable and unpleasant.

### DISCUSSION.

Mr. F. W. RICHARDSON had at one time used Clarke's method quantitatively, but had given it up qualitatively in favour of one where the sulphides were oxidised with hydrogen peroxide and ammonia, and the arsenic precipitated as magnesium ammonium arseniate, the antimony being then converted into hydride.

Dr. RAWSON said that this still left the exact difficulty he especially sought to avoid, *viz.*, the separation of the antimony and the tin after removal of the arsenic. Moreover, the complete precipitation of the arsenic as the magnesium salt required much time.

In reply to Mr. C. RAWSON, the author thought his method would work for the estimation of tin in the ash of small pieces of cloth where chromium and aluminium might be present.

Mr. F. W. RICHARDSON considered, in connection with the precipitation of magnesium ammonium arseniate, that only a short time was necessary to bring down 99 per cent. of the arsenic provided a considerable quantity of ammonia were present.

Mr. FARRANT said he had found that when very accurate results were required, 18 to 24 hours must be allowed for the magnesium ammonium arseniate to settle out (Fresenius gives 24 to 48 hours). In the case of an estimation where arsenic was present in large quantities, a great amount of the precipitate came down immediately on adding the magnesia mixture, but nothing like the whole amount; and in the case of an estimation where the amount was only small, say, in refined copper containing one-tenth per cent. arsenic, any precipitate appeared only after long standing and occasional stirring.

### THE QUANTITATIVE AND QUALITATIVE SEPARATION OF BARIUM, STRONTIUM, AND CALCIUM.

BY S. G. RAWSON, D.S.C., F.I.C.

Lecturer in Chemistry, Technical College, Huddersfield.

In the quantitative or qualitative separation of barium, strontium, and calcium there has been always a considerable amount of difficulty due to the remarkable properties of strontium which in so many respects lie almost midway between those of barium and of calcium. Hence though the estimation of both barium and calcium when present together, or of strontium when alone, presents but little trouble, yet if the whole three members of the group be taken the task becomes one of greatly-increased difficulty, it being no easy matter to ensure either the complete precipitation or the entire retention in solution, according to the process to be employed, of the strontium. To attain one or other of these ends many methods have been proposed, amongst these I may mention the following:—Fresenius recommends in his work the precipitation of the barium as silicofluoride and the subsequent separation of the strontium and calcium by means of prolonged boiling

with an enormous excess of ammonium sulphate. The particulars of the remaining processes are taken from the Journal of this Society. Fresenius and Ruppert (1892, p. 776) have investigated the relative solubilities of strontium and calcium chromates in dilute alcohol; though of value qualitatively they consider that quantitatively the method is lacking in accuracy. McElroy and Biglow (1893, p. 181) suggest the use of aqueous acetone upon these same salts, but seemingly only for qualitative purposes. In this year also (1893, p. 627) Fresenius recommends the separation of calcium as nitrate from the other nitrates by its solubility in ether-alcohol, the results he gives being very accurate. Browning (1894, p. 282) carefully examined the solubility of strontium nitrate in boiling amyl alcohol in which the salt is almost insoluble, the corresponding calcium nitrate dissolves readily, but to effect a complete separation a second treatment is necessary. Dupasquier (1895, p. 822) points out that calcium is converted into a tartrate by boiling in a liquid containing a soluble tartrate and sulphate, while barium and strontium remain as sulphates. These are estimated indirectly for quantitative purposes. Baubigny (1895, p. 1065) separates the strontium as sulphate in the presence of potassium sulphate, but the precipitation is not complete.

This bibliography though not complete includes the most important of the plans suggested. It will be noticed that in almost all of them there arises the difficulty of the slight solubility of the strontium salts in the solvents necessarily employed. Further, it rarely happens that the same method can be used both quantitatively and qualitatively. But the special objections to these methods are due to the fact that either out of the way reagents are employed, or that much and prolonged boiling is necessary to convert the given salts into the required modifications. Both these are hindrances in the way of quantitative analysis and are most serious detriments to qualitative work.

The principle of the separation upon which I have worked, depends entirely upon the behaviour of the nitrates of these three metals towards concentrated nitric acid. The method is also readily applicable to qualitative analysis: the nitrates of barium and of strontium are quite insoluble in this acid, whilst calcium nitrates dissolve very rapidly. That barium nitrate is insoluble appears to be accepted, but there is considerable divergence of opinion as regards the strontium salt, thus, Wurtz (Am. J. Sci. (2) 25, 377) states that it is sparingly soluble in concentrated nitric acid, whilst Schultz (Zeit. Ch. (2) 5, 537) considers it to be insoluble. The experiments by which I sought to settle this initial contradiction were as follows:—The nitric acid used and which was bought as pure was redistilled, the water also being similarly treated. In the case of both the nitric acid and of the water, portions upon evaporation either left no residue or one which it was not possible to weigh. The carbonate was obtained, at different times, from Germany and as being perfectly pure. I may here mention that it is most difficult to procure pure strontium carbonate. All the material which I obtained invariably contained traces of calcium in amounts varying from 0.25 per cent. to even 2 per cent. The presence of this impurity caused me great inconvenience and at first much loss of time. In order to purify the carbonate a considerable quantity was converted into nitrate and thoroughly stirred with nitric acid, filtered, and the residue dissolved in water and precipitated as carbonate, washed and dried. In the spectro-scope no trace of the calcium lines were now visible. So satisfactory and rapid is this method that I would recommend it strongly as being the most easy and the most safe for the purification of strontium from calcium salts. I may here mention that throughout my experiments I always used the carbonates of the metals partly because of the much greater convenience and certainty in weighing and also because the carbonates are far more likely to be required for estimation under usual conditions than the nitrates, and therefore it seemed advisable to work upon the more commonly occurring body.

The pure carbonate was treated with dilute nitric acid and evaporated to dryness upon the water-bath. Pure concentrated nitric acid (sp. gr. 1.445) was then added and the mixture kept well stirred for many hours, in some

cases three days. The solution was then filtered through filter paper or glass wool and the filtrate evaporated to dryness taken up with a little hydrochloric acid and again evaporated. The residue gave, in the spectro-scope, no trace of the strontium lines, but consisted of small traces of sodium and iron sulphates derived from the acids employed, and of celluloid matter arising from the filter paper, when used. Similar experiments were repeated many times varying the amounts of carbonate and of nitric acid, but only upon one occasion, in one of my earlier experiments, did I distinguish the strontium lines. I had treated some 3 grms. of the carbonate with nitric acid, and upon filtering and evaporating to dryness the residue clearly contained strontium. This was due to the solution of traces of the nitrate, the nitric acid having become diluted by the considerable amount of water formed in the conversion of the carbonate into nitrate. On all subsequent occasions I invariably evaporated the nitrate to dryness upon the water-bath and then took up with fresh nitric acid. Under these conditions the reaction was only as between the nitrate and nitric acid and the strontium lines did not again become visible in the filtrate. Hence strontium nitrate is insoluble in concentrated nitric acid. Direct experiments upon barium nitrate showed this salt to be also insoluble, whilst calcium nitrate readily dissolved. As regards the nitric acid, I prefer the specific gravity to be about 1.46 (corresponding to 80 per cent. of the acid) or even higher, but for most purposes the ordinary acid of specific gravity 1.42 (containing 70 per cent.  $\text{HNO}_3$ ) will suffice.

The actual quantitative estimation of these elements carry out in the following manner:—The carbonates are evaporated with nitric acid, either in a beaker or in a porcelain dish, preferably the latter, upon the water-bath until the mass is quite dry. Concentrated nitric acid is added in excess, and the mixture kept well stirred. The crystals settle out after each stirring very rapidly, and the clear supernatant liquid is poured through a double filter paper which has been moistened previously with concentrated nitric acid. The residue may be washed either with the concentrated acid by decantation, a method to which the mass from its crystalline nature readily lends itself, or in the customary way upon the paper.

The filtrate is evaporated either to dryness, taken up with hydrochloric acid, and the calcium precipitated as oxalate, or evaporated down with sulphuric acid, and the residue after ignition weighed as sulphate.

The remaining nitrates are dissolved in water, and the solution made alkaline with ammonium hydrate, acidified with acetic acid, and the barium precipitated as chromate. The filtrate is warmed with hydrochloric acid and alcohol until the chromate is reduced, the chromium precipitated as hydrate and filtered off. The filtrate is evaporated to dryness upon the water-bath with a little sulphuric acid. The residue is treated with dilute alcohol and washed, and the residual strontium sulphate weighed as such. Two out of the different test analyses, which I have made, give the following results:—

	1.		2.	
	Taken.	Found.	Taken.	Found.
Barium carbonate .....	0.5393	0.5379	0.2127	0.2130
Strontium carbonate ...	0.2578	0.2584	0.4583	0.4576
Calcium carbonate.....	0.5473	0.5470	0.2773	0.2789

For the qualitative separation the above process may be much simplified. The carbonates, after treating with the minimum amount of nitric acid, are boiled down just to dryness; then treated with concentrated nitric acid, the paper having been first moistened with this acid, filtered, and the residue washed by decantation. The filtrate is diluted considerably with water made alkaline with ammonia, and the lime thrown down as oxalate. The residue is dissolved in water (the filter paper will not disintegrate unless boiling cold water be used), made alkaline with

ammonia, acidulated with acetic acid, and the barium precipitated as chromate. To the filtrate is added hydrochloric acid, and it is boiled with a little alcohol, and the chromium precipitated as hydrate, which is filtered off. To the filtrate sulphuric acid is added, and the solution heated; if necessary alcohol is added, the strontium coming down as sulphate. The separation of the chromium as hydrate is not in all cases necessary.

The process can be carried out very rapidly, and, further, is a complete separation of these three metals, and does not rest upon grounds such as the length of time allowed for boiling or standing, or the greater or lesser concentration of solutions.

#### DISCUSSION.

The CHAIRMAN (Mr. FAIRLEY) in opening the discussion, referred to the necessity for a good separation of these metals, he himself having experienced the want in the analysis of waters such as those of Harrogate.

Considering the fact that chalk dissolved only with difficulty in concentrated nitric acid, he should have imagined that calcium nitrate would hardly have been sufficiently soluble in concentrated nitric acid for purposes of separation.

Dr. S. G. RAWSON had observed the difficulty of dissolving chalk in strong nitric acid, but pointed out that in his method dilute nitric acid was used to convert the carbonates, a procedure which eliminated the difficulty, and although chalk might be only soluble with difficulty in strong nitric acid, calcium nitrate was easily soluble in that medium. He also drew particular attention to the impurity of the strontium carbonate supplied as pure, stating that he had invariably found some calcium present, and in some cases even as much as 2 per cent.

Prof. PROCTER raised the question as to whether, in the spectroscopic examination which the author had used to determine the completeness of the separation, a trace of one metal might not easily be obscured by an excess of another.

The CHAIRMAN, replying, stated that masking might easily take place, and cited a case where a considerable proportion of lithium was introduced into a water, and was unrecognisable spectroscopically until the other salts (of sodium and potassium) had been removed.

Prof. SMITHells considered that masking might be due to the continuous light generally present in the predominating spectrum, and, referring to electric spectra, cited the recently observed case of Helium and Argon. He also referred to the masking of the carbon spectrum of a Bunsen burner, which took place immediately the flame was coloured by a foreign substance. He considered that examining the spark direct from the liquid was less likely to lead to masking of traces than evaporation and heating of the solid residue on a wire.

He also remarked that the lines at the blue end of a spectrum are less easily masked than those at the red, as, e.g., in the case of lithium.

Prof. H. R. PROCTER was of opinion that masking might be a chemical rather than an optical effect.

Dr. RAWSON thought that as regards the detection of traces of strontium and of calcium for the present purpose, the delicacy of the flame reaction in the spectroscopic was sufficient.

### NOTES ON RESIDUAL CYANIDE SOLUTIONS, AND A METHOD OF EXAMINING THEM.

BY CHAS. J. LELIS, F.R.C.

THE extraction of gold and silver from ores, tailings, &c., by means of weak solutions of the alkaline cyanides, is one of the youngest of the chemical industries, but is fast taking rank among those of the first importance. As far as I am aware, less than ten years ago, hardly any, if any at all, gold or silver was being extracted by this means on a practical scale, and already to the value of several millions sterling per annum is being produced, a large part of which is recovered from tailings which had, to a great extent, been cast aside as valueless, and in many cases considered an unavoidable nuisance by the mine owners, until this process had been devised and proved competent to deal with them profitably.

For the intelligent carrying out of the cyanide process, a more considerable knowledge of the chemistry involved in the details is necessary than might be at first supposed; of course, certain ores, &c., are very much more easily dealt with satisfactorily than others, and in some cases more or less satisfactory results may be obtained by means of the process in the hands of one who knows little or nothing of the chemistry of the more minute details; this, however, may be taken to be the exception rather than the rule, and hardly ever will the treatment be effected in the most economical way possible under superintendence of this class.

Of recent years, valuable contributions to the literature on the subject have from time to time been made by James, Bettel, Feldtmann, Batters and Clennell, and others; but the field is such a wide one, that I think it is unnecessary for me to make any apology for recording the following notes, even though they are partly a recapitulation of some facts now more or less well known, in addition to a statement of others which are perhaps less generally known.

When ores, tailings, &c., are treated with weak cyanide solution, a certain amount of free cyanide is consumed or destroyed, and the cause of this consumption may be tabulated under three general headings, supposing zinc is employed as the precipitant of the precious metals, viz.:—

- (a.) Its combination with certain constituents of the material under treatment.
  - (b.) The action of the zinc in the precipitating boxes on it.
  - (c.) Its decomposition by exposure to atmospheric influences, prolonged contact with water, &c., &c.
- (a.) Under this heading of course comes the small amount of cyanide actually consumed in forming double cyanides of gold and of silver with alkaline cyanide, during the solution of these metals; this item of the consumption is generally so comparatively minute as to be practically of little or no importance.

There are few, if any, gold-bearing materials which do not contain at least a small quantity of some compound of iron in the ferrous state, a portion of which is in a condition in which cyanide can readily attack it, and form ferrocyanide. It has been stated also that, in some cases, cyanide attacks certain ferric compounds and forms ferricyanide. As far as my experience goes, this action is, however, at most, trifling, compared to its action on ferrous compounds, and it is partly for this reason that the addition of lime or soda to ores, &c., which have become acid through weathering, and the subsequent oxidation by the air or otherwise, before actual treatment by cyanide, is so beneficial in preventing excessive consumption of cyanide in the treatment of such material.

Zinc is another metal which is occasionally dissolved out of ores, &c., probably by the cyanide forming double cyanide of zinc and potassium ( $ZnCy_2 \cdot 2KCy$ ) (this point

will be referred to again below): however, many of the compounds of zinc existing naturally in minerals resist the action of cyanide much more completely than would be expected from studying the action of cyanide on similar compounds produced artificially by precipitation from solutions.

When copper is present in ores, &c., at least a portion of it is almost invariably attacked by the cyanide, cupro-cyanide of potassium ( $\text{Cu}_2\text{Cy}_2\cdot 2\text{KC}_y$ ) being mainly formed, accompanied, if the copper happens to exist in the cupric condition, with liberation of cyanogen, which, however, will form cyanide and cyanate of potassium if free alkali is present (which is generally the case), or react with soluble sulphides to form sulphocyanide, and possibly also go to form a little oxalate, oxamide, &c., &c. Arsenic is also often found in cyanide solutions after use, but has probably been dissolved by the alkali in the solution rather than by the cyanide *per se*. In somewhat exceptional cases, manganese, nickel, and even a little cobalt have been found in residual solutions, probably existing as manganicyanide, double cyanide of nickel, and potassium and cobaltcyanide.

Much depends on the physical condition in which compounds of the bases exist in ores, &c., as well as on their chemical composition. One sometimes comes across ores, &c. containing a high percentage of copper in the form of sulphide, physically in a very hard condition, and finds little or no copper dissolved from them by cyanide.

While the bases are being attacked by the cyanide and forming double or compound cyanides, other compounds are being of necessity simultaneously produced. For instance, while the metal is being removed as cyanide from, say, a sulphide, alkaline sulphide is being simultaneously produced in the solution, which may further go partly to form sulphocyanide, especially if cyanogen is present also; thus,  $2\text{Cy} + \text{K}_2\text{S} = \text{KC}_y + \text{KC}_y\text{S}$ .

This formation of sulphide in solution is a matter of considerable practical importance, and if it takes place to any extent, means should at once be adopted for its removal from solution, as, even in comparatively minute quantity, its presence greatly retards, or even partly prevents the solution of gold and silver by cyanide. I first noticed this fact about eight years ago, while investigating the effect of the addition of various salts to cyanide solution in relation to its action on the constituents of ores, &c. I found that chlorides, sulphates, nitrates, ferro-cyanides, and even hypo-sulphites and sulphocyanides, &c., when present, even in considerable quantities, have, as a rule, little or no bad effect, but that even as little as one part of alkaline sulphide in 20,000 of solution has often quite a marked effect in retarding the action of cyanide in dissolving gold.

It having been thus found of importance to avoid, as far as possible, sulphide remaining in solution, in this connection MacArthur and myself some years ago took out a patent for the addition of certain salts of lead, &c. to the solutions where found necessary for its removal.

It is the practice to employ the same cyanide solution continuously for a more or less prolonged period, simple alkaline cyanide being added from time to time. It was at first feared that by doing so, the impurities, such as zinc salts, sulphides, &c., &c., would accumulate in the solutions to such an extent as to make them in time quite unfit for use; this fortunately appears seldom to be the case, however, in practice, as in addition to the formation of such compounds, certain reactions are also taking place in the course of employing these residual solutions, tending to remove or decompose at least some of the impurities. For instance, a portion of the zinc tends to be removed as sulphide during the action of the solution on pyritic material, or by reaction with any sulphide in the solution, in the latter case a corresponding regeneration of simple cyanide simultaneously taking place; a portion of the sulphide may also be decomposed or removed during its passage through the zinc box, or by reaction with zinc in solution, to form the insoluble sulphide, and another portion by slow transformation into sulphocyanide, &c.

(b.) The consumption of cyanide in the zinc extractors (if this really does take place in presence of free alkali) is

probably mainly due to the formation of double cyanide of zinc and potassium in accordance with the equations—

The whole question of the reactions taking place in the zinc extractors has been ably and somewhat fully discussed by James, in his paper on "Cyanide Practice," read before the Institute of Mining and Metallurgy in May 1895.

(c.) The decompositions which come under this head, namely, prolonged exposure of cyanides to the influence of the atmosphere, water, &c., involve reactions of an even more complex and deep-seated nature than those under the former two headings. I do not propose here to enter into a discussion of these reactions, but simply to state that the products of decomposition may include any or all of the following, *viz.*, cyanates, cyanurates, urea, carbonate of ammonia, formates, and possibly oxalates, oxamide, &c., &c. The direct effect of the accumulation of these various compounds in residual solutions on the efficiency of such solutions for extracting gold, does not appear to have yet been very fully studied; it is, however, known that the presence of any considerable quantity of such a compound as ammonium carbonate tends to accelerate the formation of such bodies as paracyanogen, azulmic acid, &c., in the solutions, and generally the destruction of cyanide.

In the examination of ores, tailings, &c., for treatment by the cyanide process, one of the first things to be determined, after making preliminary assays, is the amount of cyanide consumed by the material, and if this is found to be in any way considerable, the cause of such consumption should be determined approximately. It is usually found that when the consumption is at all high, a large part of the total consumption takes place almost immediately on mixing the ore and solution, this being generally at least more than half the total consumption which will take place during prolonged contact. The determination of this portion is made as follows:—If the material has been found to be acid, it is mixed with a slight excess of caustic soda solution and agitated with it for half an hour or so, with free access of air; the requisite cyanide solution is then added and agitation continued for ten minutes, after which the liquor is filtered off and the cyanide remaining determined; the difference between this amount and the quantity employed giving the consumption. Subsequently a similar experiment is carried out, agitating with the cyanide for a number of hours.

To determine approximately the cause of consumption, an aliquot portion of the liquor from one or other of the above experiments is taken, evaporated nearly to dryness, and then drenched with strong sulphuric acid, and warmed to thoroughly decompose any compound cyanide, and the excess acid driven off; the metals will now be in the form of sulphates, and in a suitable condition for separation and determination by the ordinary analytical methods. The zinc is generally taken to have existed as double cyanide of zinc and potassium, the copper as cupro-cyanide of potassium, and the iron as ferro-cyanide of potassium.

The consumption of cyanide accounted for by calculation from the bases found in solution generally falls somewhat short of that determined by testing the cyanide remaining undecomposed after use; the difference between the two is taken as being decomposition, due to causes other than the direct action on bases. It is almost invariably found that the total consumption of cyanide in practical working is very considerably less than that found in small-scale experiments; this smaller consumption is considered to be mainly due to the proportionately smaller surface of solution exposed in large than in small operations; and to reactions, some of which are referred to above, tending to the regeneration of simple cyanide in the solution. The portion of the consumption due to direct action of the cyanide on bases, as determined in the above manner, is, however, probably more or less the same on whatever scale the treatment may be carried out.

The determination of free alkaline cyanide in the solutions to be employed, or remaining in solution after use, is almost invariably made by Liebig's method, *viz.*, titration with silver

nitrate solution until a permanent cloud is obtained. In the case of pure solutions of cyanide, or even of those containing considerable quantities of most other salts commonly met with, this method gives results of great accuracy, *viz.*, within one part of cyanide in one million parts of water being able to be determined. The presence of ammonia interferes with the test, from the fact that the cloud, which consists of silver cyanide, is dissolved by the ammonia; this, however, is easily corrected for by the addition of a little iodide of potassium. As soon as all the cyanide is in the form of double cyanide of silver and potassium, the succeeding drop of silver solution forms silver iodide, which is practically insoluble in ammonia. If sulphide is present it must be removed by means of lead carbonate before applying the test. The presence of double cyanide of zinc and potassium along with alkaline hydrate, or even carbonate, however, entirely does away with any accuracy in this test for the determination of free alkaline cyanide in distinction to the cyanide existing in the double zinc cyanide, if this latter really does exist in solution in presence of the free alkali. In a paper, "On the Technical Analysis of Cyanide Working Solutions," read before "The Johannesburg Chemical and Metallurgical Society" in August 1895, Bettel draws particular attention to this, and discusses it somewhat fully; and also to the fact that if sufficient caustic alkali is present in, or is added to a solution containing double zinc cyanide, on adding some iodide and titrating with silver nitrate, the point at which opalescence begins indicates sharply the total cyanogen present in the double cyanide—of course, in addition to any also existing as simple alkaline cyanide; and even that the presence of alkaline carbonate interferes with the correct testing of simple cyanide in presence of double zinc cyanide. He suggests the following equations to explain these facts:—

and in the case of the presence of excess of alkaline carbonate

If we can accept these equations as correctly describing what takes place, it follows that no double cyanide of zinc and potassium can form, or exist, in solution so long as excess of free caustic alkali, or even carbonate, is present, and consequently that no actual consumption of simple cyanide, to form double cyanide of zinc and potassium, will take place during the passage of the solutions through the zinc extractors, or during their contact with zinc compounds, contained in ores, &c., so long as sufficient free alkali is present in the solution. The equations which I believe are generally accepted as representing the main reactions which take place in the zinc box, and which have been adopted by James in his paper on "Cyanide Practice," are as follows:—

- (a.)  $2KAuCy_2 + Zn = K_2ZnCy_4 + Au_2$
- (b.)  $4KCy + Zn + H_2O + O = K_2ZnCy_4 + 2KHO$
- (c.)  $4KCy + Zn + 2H_2O = K_2ZnCy_4 + 2KHO + H_2$
- (d.)  $Zn + 2KHO = K_2ZnO_2 + H_2$

and further, as suggested by Feldtmann,—

in addition to others which I need not recapitulate. The last of these is interesting as showing how the hydrogen evolved may of itself play an important part in the precipitation of the gold in the zinc box.

In the same paper he expresses his opinion, and gives his reasons for so doing, that the reaction in the zinc box is rather between the caustic alkali and the zinc, than between the cyanide and the zinc.

The question as to whether a mixture of dilute solutions of zinc double cyanide and caustic alkali remains as such, or that the compounds react to form free alkaline cyanide and zinc-potassic oxide, is one which is worth discussing, and the subject seems to be deserving of even further investigation than has yet been made of it. It is, however, one of those cases concerning which it is difficult to prove the truth of one or other view by direct tests, as generally the mixed solution would behave in the same way towards reagents in whichever of the two ways the various elements were combined.

In connection with this whole subject, I may mention that the effect of the presence of free alkali on the titration by silver of cyanide solutions containing zinc came under my notice many years ago, and during 1890-91, in conjunction with Adam Dickie, I carried out an investigation of the matter, and before it had proceeded far we considered the reason to be that a mixture of zinc double cyanide and caustic alkali or alkaline earth did react to form simple cyanide and the double oxide of zinc and the alkaline metal, and we then lodged a provisional specification to patent the addition of caustic alkali or lime to residual solutions, supposed to contain double zinc cyanide, in sufficient quantity to effect this reaction; or preferably to cause such solution to flow through or over beds of lime. For certain reasons we did not complete the patent, but I am still strongly of opinion that especially the second of these methods, *viz.*, from time to time flowing the residual solutions over or through beds of lime, where it could be applied cheaply enough, would, in many cases, be found most beneficial to such solutions, by revivifying them, removing certain impurities from them, and generally bringing them into a more fit and active condition for continued re-use than if not so treated.

During the course of our investigation we carried out numerous trials on various samples of ores, using solutions of double zinc cyanide, or of residual solutions practically free from simple cyanide, but containing double zinc cyanide alone, and after addition of caustic alkali or passage through a lime filter; also, in some cases, after treatment with a soluble sulphide and removal of excess of sulphide by lead carbonate; and arrived at the following conclusions, *viz.*, that in almost all cases some of the gold and silver is extracted from ores, &c. by the use of double zinc cyanide alone, and that in most cases the extraction is better with the solution treated with alkali, or by sulphide, than not so treated. We also proved that part of the zinc is removed from zinc double cyanide by contact with certain pyritic ores, by mixing a pyritic ore with a solution of double zinc cyanide and agitating for some hours, and determining the zinc in solution before and after use.

A very large excess of caustic alkali in the solutions should, however, be avoided, as its presence tends to cause reactions to take place, or at least to intensify them with some of the constituents of the ores, &c., such as sulphides, arsenic compounds, &c., &c., and to thus introduce objectionable impurities into the solution.

The fact that all the cyanogen in zinc double cyanide, on addition of excess of free alkali, can be determined by silver solution, as stated above, may be explained in another way than by assuming the mixture to have formed free cyanide and zinc-potassic oxide; *viz.*, that the reaction does not take place except in presence of another metal, such as silver (and probably gold), which has a superior affinity to zinc for cyanogen—at least, to the extent of the formation of the double cyanide.

I have proved the following reactions to take place on adding silver nitrate solution to solution of double zinc cyanide in absence of free alkali:—

and

This substitution of silver for zinc might be expected to take place even more readily in presence of free alkali, which, by its affinity for zinc to form the double oxide, might lend its aid in inducing the substitution. I have not tried the use of a solution of a gold salt in place of a silver, but a similar reaction might be expected to take place. These facts may possibly at least partly explain how double zinc cyanide alone, and especially in presence of free alkali, effects extraction of gold and silver from ores.

We may suppose the following reactions to take place simultaneously in presence of caustic alkali:—

the potassic cyanide portion of the double zinc cyanide, re-formed as in (b), being then acted upon further by the

silver salt, as in (u), this going on until all the zinc has been brought into the form of zinc-potassic oxide. If the caustic alkali is able thus to act as a carrier of cyanogen between zinc cyanide and silver, the fact may perhaps partly explain why the presence of free alkali in residual solutions makes them more efficient for extracting gold and silver than if it were absent.

From thermal data, zinc cyanide appears to be a much more stable compound than silver cyanide. Thomsen gives as thermal values—

$$[\text{Ag}_2, \text{Cy}_2] = 2,790, \text{ and } [\text{Zn}, \text{Cy}_2] = 53,400;$$

and thus silver would not be expected to be able to displace zinc from zinc cyanide. Thomsen's thermal values for the double cyanides are—

$$[\text{Ag}_2, \text{Cy}_2, 2\text{KC}_y, \text{Aq}] = 15,780, \text{ and } [\text{Zn}, \text{Cy}_2, 2\text{KC}_y, \text{Aq}] = 62,230;$$

from the above the following can be deduced, viz.:—

$$[\text{Ag}_2, \text{Cy}_2, 2\text{KC}_y, \text{Aq}] = 12,990, \text{ and } [\text{ZnCy}_2, 2\text{KC}_y, \text{Aq}] = 8,830,$$

the difference, 4,160, being thus in favour of the probability of the reaction—

taking place, and further experiments I have made prove that it does.

I have been unable to find a statement of the thermal value of  $[\text{ZnO}, \text{K}_2\text{O}, \text{Aq}]$ , so cannot get direct evidence regarding the probability, from thermo-chemical reasoning, as to whether or not the reaction—

will take place; however, thermally it would be represented as follows. Again taking Thomsen's figures—

$$\left\{ \begin{array}{l} - [\text{Zn}, \text{O}, \text{H}_2\text{O}] + [\text{K}_2, \text{Cy}_2, \text{Aq}] + [\text{ZnO}, \text{K}_2\text{O}, \text{Aq}] \\ \quad - 82,680 \quad + 124,680 \quad + ? \\ - [\text{Zn}, \text{Cy}_2] - [\text{K}_2, \text{O}, \text{Aq}] - [\text{ZnCy}_2, 2\text{KC}_y, \text{Aq}] \\ \quad - 53,400 \quad - 164,560 \quad - 8,830 \end{array} \right\}$$

which would necessitate the thermal value of—

$$[\text{ZnO}, \text{K}_2\text{O}, \text{Aq}]$$

being at least 19,430 for the reaction to take place without absorption of heat—a somewhat large quantity for a combination of this sort.

Bettel states that, using phenolphthalein as indicator, and titrating solutions of the following salts with acid; to  $\text{KC}_y$ , the full equivalent of acid requires to be added before the red colour is discharged; to  $\text{ZnOK}_2\text{O}$ , acid equivalent to the contained  $\text{K}_2\text{O}$ ; and to  $\text{ZnCy}_2 \cdot 2\text{KC}_y$  only 7.9 per cent. of the equivalent of acid requisite for its complete decomposition. Taking these figures, it will be seen that if the reaction  $\text{ZnCy}_2 \cdot 2\text{KC}_y + 2\text{K}_2\text{O} = \text{ZnOK}_2\text{O} + 4\text{KC}_y$  does take place, more acid would be required to be added to the mixture to discharge the red colour than to the two separate solutions used to make the mixture. In several experiments, using various quantities of caustic potash and of double zinc cyanide solutions, it has been found that the quantity of acid required for the mixture has been identical with the sum of the quantities required for the two separate solutions used to make the mixture, from which it would appear that the reaction probably does not take place.

To sum up this matter, either from experiments made or from reasoning, I still find it difficult to form a very decided opinion as to whether this reaction does or does not take place in the case of dilute solutions, but am inclined to the view that it does not.

*Analytical Examination of Residual Solutions.*—An exact direct method of determination of free alkaline cyanide in presence of double zinc cyanide and also carbonate and caustic alkali, one at least of which is almost invariably present in working solutions, is much required; but although I have made many attempts to find such, I must acknowledge to have failed in hitting upon a single one which can be considered altogether satisfactory when caustic alkali is present. In the presence of carbonate only, the addition of excess of barium chloride or nitrate decomposes this, and the filtrate from the barium carbonate

contains now alkaline chloride or nitrate in place of carbonate, which does not interfere with the test. If caustic were also present, a very cautious addition of bicarbonate to carbonate it, followed by precipitation by barium salt as above, might be of some use; but the difficulty here is to avoid adding either too much or too little bicarbonate, leaving thus in the former case excess of bicarbonate, tending to liberate hydrocyanic acid, and in the latter a portion of the caustic uncarbonated.

Although as a rule the partial examination of residual solutions by determinations as indicated above is all that is often made, a fuller examination of them from time to time may afford valuable information relating to their condition and composition, especially after they have been in use for a considerable time; and possibly the cause of extractions of the gold by their use being not altogether satisfactory, when such is the case, might be thereby traced.

We are indebted to Bettel and Feldtmann for recent publications of their investigations relating to the analysis of cyanide solutions, &c.; and in contributing the following notes it is not in any way my desire to question the accuracy of the methods proposed by these chemists, but solely to offer a choice of alternative methods of determination of some of the various constituents of these solutions.

I will assume that the residual solution to be examined may contain any or all of the following, viz., free alkaline cyanide, double zinc cyanide, alkaline ferrocyanide and sulphocyanide, cyanates, urea, salts of ammonia, cyanurates, oxalates, &c., in addition to hydrates, carbonates, chlorides, sulphates, and sulphides of the alkalis. In the first instance I assume the absence of copper compounds, except possibly in very minute quantity, as these interfere considerably with some of the methods of determination referred to below; but in a note at the end of this paper I refer shortly to this interference. Cases in which copper in considerable quantity finds its way into the cyanide solution are certainly not uncommon; in such cases, at least part of the copper will be removed on passing through the zinc extractors; but there are far more cases in which only a minute quantity, if any at all, is in solution.

(1.) *Cyanogen Compounds, &c.*—On shaking up the solution with excess of ferrous hydrate or carbonate and some caustic potash (which must be free from chloride), the cyanogen of the simple and double zinc cyanides is all brought into the condition of yellow prussiate, the reaction being complete in a very short time, thus:—

and

The solution is filtered from the excess of ferrous hydrate and divided into two portions, the one being used mainly for determining the yellow prussiate and sulphocyanide separately, and the other for determining yellow prussiate, sulphocyanide, and chloride all together. For these determinations an adaptation of Volhard's well-known method of titration with silver nitrate in presence of nitric acid has suggested itself to me, which for several reasons I prefer to employ to methods in which titration by permanganate is employed, as these latter are often so apt to have the accuracy of the determination of the particular body under consideration interfered with by the presence of other reducing agents in the solution. To the one portion a measured quantity of decinormal silver solution is run in in excess, the mixture acidified with nitric acid to dissolve any hydrate and cyanate of silver, &c. which may have been precipitated, and the remaining precipitate of ferrocyanide, chloride, and sulphocyanide of silver can then be filtered off, preferably through glass-wool or asbestos, and the excess of silver determined in the filtrate by decinormal sulphocyanide, using persulphate of iron as indicator; in place of filtering, the turbid mixture may be made up to a definite bulk with water, shaken up, and the precipitate allowed to settle, and the silver determined in an aliquot portion of the clear supernatant solution, the space occupied by the precipitate being too little to seriously affect the measurement. The necessity for removal of the precipitate at all is owing to the

presence of the silver ferrocyanide, which would react with the iron indicator, and thus interfere with the determination.

To determine the ferrocyanide alone in the other portion of the amin solution, it is poured slowly into a warm solution of a per-salt of iron containing some free acid, the Prussian blue filtered off and washed, the precipitate decomposed with caustic potash, the iron hydrate filtered off, and the yellow prussiate in the filtrate determined, either by the silver method as above, or, if preferred, by acidifying and titrating with standard permanganate.

The filtrate from the Prussian blue will contain all the sulphocyanide, and after precipitation of the iron by caustic potash and neutralisation of the filtrate from the iron hydrate, in part of this solution the sulphocyanide can be determined by the method described by Barnes and Liddle (see the *Journal of this Society*, Vol. 2, p. 122, and also Sutton's book on Volumetric Analysis, p. 177), *viz.*, precipitating as sub-sulphocyanide of copper in presence of a reducing agent with standard copper solution, the presence of any excess of copper being tested for by bringing a drop of the solution in contact with a drop of yellow prussiate solution, a brown coloration forming as soon as there is a trace of copper in excess.

The cyanogen existing in the simple cyanide and double zinc cyanide may be determined by titration of the original solution with silver solution in presence of excess of caustic alkali and iodide of potassium, as indicated above. In carrying out this determination, I find it advisable to use as pure potash as possible, and even with this I have noticed a slight white opalescence form shortly before the yellow cloud, due to iodide of silver being formed; but, as far as I can judge from experiments with pure double cyanide of zinc, this slight white opalescence may be neglected, and the point when it changes to the yellow opalescence (quite a sharp point) be taken as the one indicating full conversion of all the cyanide into double cyanide of silver and potassium. The double zinc cyanide alone can be calculated from the determination of the zinc in the solution; by knowing the total cyanide, including the ferrocyanide, determined as stated above, all in the form of ferrocyanide, and the simple and double zinc cyanide, it is easy to calculate the ferrocyanide which existed as such in the solution being tested.

(1a.) An alternative method of determining the above constituents is as follows:—Place a suitable amount of the residual solution in a retort with some zinc sulphate solution; this latter is to ensure sufficient zinc being present to fix all the ferrocyanide, on acidifying, as zinc ferrocyanide, which is practically unattacked by moderately dilute sulphuric acid; then add an excess of dilute sulphuric acid, and distil through a condenser, catching the distillate in excess of caustic alkali; this latter can then be titrated with silver solution, and the whole of the hydrocyanic acid which had existed as simple cyanide and double zinc cyanide is thus determined. If the solution had contained any sulphide, this is preferably removed by shaking up with a little lead carbonate and filtering before placing in the retort. In the still there now remains all the hydroferrocyanic acid as ferrocyanide of zinc in the form of a precipitate insoluble in the weak sulphuric acid, and the sulphocyanic and hydrochloric acids, &c. in the solution. The precipitate is filtered off, decomposed by pure caustic potash, and the ferrocyanide determined by silver by the adaptation of Volhard's method as described above, the sulphocyanic and hydrochloric acids together by Volhard's method, and the sulphocyanic alone by Barnes and Liddle's method referred to above.

(2.) *Carbonates, Oxalates, and Sulphates.*—These can be determined as follows:—Three quantities of the solution are taken, and excess of barium salt added to one, and of calcium salt to the other two. The barium precipitate is treated with hydrochloric acid, and the barium sulphate left undissolved determined in the ordinary way. One of the others is ignited to convert the oxalate into carbonate, and the total carbonate thus produced determined by dissolving in a known quantity of standard hydrochloric acid in excess, and, after boiling off the carbonic acid, determining the excess of acid. The third precipitate is put in

a large basin of water, and the carbonate and oxalate decomposed by a small excess of hydrochloric acid, and the oxalic acid determined by standard permanganate in the usual way, warming the solution to promote the reaction.

(3.) *The Bases in Solution.*—These are determined as described in an earlier part of this paper. During the course of making this determination, if desired, an approximate estimation of the total solids in the solution may also be made by evaporation to complete dryness and weighing the residue, though at best this will only give a rough approximation, as certain of the solid constituents of the original solution will have been decomposed or altered during the evaporation, and probably also some portion of them, such as the ammonia compounds, have been volatilised.

(4.) *Sulphide in Solutions.*—It is unusual for more than a small quantity of sulphide to be found in residual cyanide solutions, but there is fortunately a most delicate way of estimating an extremely minute quantity of it rapidly, even in presence of the various other constituents of these solutions. By means of a dilute solution of a lead salt, less than one part of sulphide in 1,000,000 parts of solution can be detected with comparative ease, and an approximate determination of the quantity in a solution as dilute as this be made. There are a variety of ways in which a lead solution of known strength can be employed to effect the determination. Of these I prefer the following:—A convenient strength of lead solution to employ is one of which 100 measured grains is equivalent to 0.01—0.02 of a grain of  $K_2S$ . The solution to be tested, if very highly coloured, is first decolorised by any suitable well-known means. This, however, is often unnecessary, a slight tinge of brown not seriously affecting the accuracy of the determination. A rough determination of the sulphide is then made colorimetrically by means of the lead solution, to find out if it contains more or less than about 1 part of sulphide in 20,000 parts. If the quantity is less than this, the solution is still further diluted with recently boiled and cooled distilled water until it contains = only 4—6 parts of potassic sulphide per million, which is about the most convenient strength to test. Two quantities of 5,000 grains each, of the diluted solution are measured out into two 20-oz. flasks placed on a white surface. Successive quantities of 10 grains or so of the lead solution are added to each flask, until the last addition to one fails to make its contents darker than that of the other, when the sulphide is calculated from the quantity of lead solution employed, omitting this last addition. As each addition is made, it is easy at first to see a brown cloud forming at the point where the lead solution enters the one being tested: when this fails to be noticed, it is an indication that the end point is nearly reached. Working in this way, I find that the sulphide can be determined to within about 2—3 parts per 10,000,000 of solution, even when it is slightly coloured. If the original solution contains more than about 1 part of sulphide in 20,000, a suitable quantity of it, say from 100—1,000 grains, according to the amount of sulphide suspected to be in it, is put into a flask and the lead solution run in until the precipitate cannot be noticed increasing perceptibly: about 1—2 c.c. or so is then filtered through several thicknesses of filter paper, the filtrate generally being of a brown colour, half of it is placed in each of two small test tubes, a drop or two of the lead solution is added to one test tube, and if its contents become darker than that of the other, their contents are returned to the main solution and further lead solution added, and so on until this darkening no longer takes place. Of course, if on making the first test no darkening has taken place, too much lead solution has been added, and a new quantity of the original solution must be taken, and the test repeated, adding a smaller quantity of the lead solution at the first. The presence of the other constituents of the solution appear to have no effect on the accuracy of the determination made in this way.

(5.) *Cyanates, Cyanurates, Ammonia Salts, and Urea.*—From experiments on artificial mixtures of these in presence of cyanides, ferrocyanides, chlorides, &c., I find that their quantities can be approximately determined as follows:—To the solution, barium nitrate solution in slight excess is added to decompose the carbonates, and cyanurates if

present in moderate quantity; if the presence of caustic soda is suspected, a little carbonic acid water in the least possible excess having been added to carbonate it before addition of the barium solution. To the filtrate from the barium carbonate and cyanurate, silver nitrate solution is run in, if the solution is almost neutral chromate being employed as indicator of full precipitation, if not, a slight excess of silver may be employed. The solution is filtered off and the filtrate is retained for estimation of the ammonia salts and urea, as described below. The precipitate, which may consist of silver cyanide, ferrocyanide, sulphocyanide, chloride, &c., in addition to cyanate, is shaken up with dilute nitric acid to dissolve the cyanate, and the quantity of silver in solution determined by Volhard's method, after removal of the insoluble portion of the precipitate, and the cyanic acid calculated from it. If cyanurate is suspected to be present, the above can be repeated, using calcium nitrate in place of barium nitrate; calcium cyanurate, being soluble in water, will then be in the filtrate from the carbonate precipitate, and can be determined along with the cyanate, as above. To the original filtrate from the total silver precipitate a little common salt is added, if excess of silver had been employed, to remove this excess, the silver chloride filtered off, and the filtrate placed in a retort and distilled, with a slight excess of caustic potash present, for a comparatively short time, keeping the liquid just barely boiling, the distillate being caught in a measured quantity of  $\frac{1}{2}$  normal hydrochloric acid.

The ammonia in the distillate is then determined by nesslerising, or by titration of the acid left unneutralised. If the distillation is carried out at a low enough temperature, and is not too prolonged, and no great excess of caustic potash is employed, little, if any, of the nitrogen of the urea passes over as ammonia with the distillate, most of the urea remaining undecomposed; and its quantity can be determined in the solution left in the retort by the well-known method of decomposition by hypobromite of soda and measurement of the nitrogen evolved; or, if preferred, the ammonia and urea can be determined together by this method in a portion of the filtrate from the silver precipitate.

(6.) *Alkalinity.*—It is advisable to determine the alkalinity of the stock of working solution from time to time. This may be done, comparatively, by titration in the cold with acid, employing some one selected indicator; but, as Bettel has pointed out, the point of neutralisation of the various constituents of the solution differs with certain indicators, and therefore fuller information as to the character of the alkalinity may be obtained by making several titrations, using different indicators; also by titration before and after precipitation by barium or calcium salt, and removal of the precipitate. It may also be sometimes useful to determine the quantity of dilute acid consumed in decomposing certain constituents of the solution, by warming with an excess of it and titrating that remaining.

*Note on the Effect of Copper in Solution.*—As mentioned before, the presence of any considerable quantity of copper in solution tends to impair the accuracy of some of the methods of determination described above; this applies specially to those given in paragraph (1), *viz.*, the determination of the simple and double cyanides, as distinct from ferrocyanide, and also of the sulphocyanide. The reason for this is that cuproso-cyanide of potassium behaves in many ways differently towards certain reagents to zinc potassio-cyanide; for example, it does not yield ferrocyanide of potassium when treated with ferrous hydrate and caustic potash; its hydrocyanic acid cannot be determined directly by titration with silver solution, either in presence or absence of caustic potash; it is decomposed and gives off its hydrocyanic acid when distilled with dilute sulphuric acid, though not so readily as zinc double cyanide; if, however, any ferrocyanide, even of zinc, is present in the retort, the copper as set free from the cuproso-cyanide will displace the zinc and form a ferrocyanide of copper; ferrocyanide of copper is generally taken to be insoluble in dilute sulphuric acid, but it does not in fact resist its action when boiling nearly so fully as zinc ferrocyanide does, but is very slowly decomposed by it, giving off hydrocyanic acid; this decomposition is, however, so slow

that to obtain all the hydrocyanic acid from it by distillation with weak acid entails prolonging the distillation for an almost impractical length of time; were this not so, the addition of a copper salt to ferrocyanide of zinc and distillation of the mixture with weak acid might be employed as a means of obtaining hydrocyanic acid from the latter. The hydroferrocyanic acid in combination as a ferrocyanide of copper can, however, be determined just as readily and accurately as that in ferrocyanide of zinc by the adaptation of Volhard's method of titration with silver solution referred to above, the copper hydrate being filtered off after the decomposition by caustic alkali. The total hydrocyanic acid can, however, be determined, and also a roughly approximate separation of the hydrocyanic acid existing as simple and double cyanide from that existing as ferrocyanide be made, by distillation with weak sulphuric acid as described in paragraph (1a) above (a little of the copper ferrocyanide formed, if ferrocyanide is also present, probably being decomposed during the distillation). The cyanide found in the distillate will thus correspond to a little more than that which actually existed in the solution as simple and double cyanide, and the hydroferrocyanic acid estimated in the insoluble ferrocyanides left in the retort, by the silver titration method given above, to a little less than that which actually existed as ferrocyanide in the original solution.

I am still experimenting with solutions containing copper, with a view to arriving at some modifications of the analytical processes which will allow of the various determinations being made, in the case of such solutions, with the same degree of accuracy as if little or no copper were present.

In conclusion, I may remark that many of the points touched upon in this paper would probably afford suitable subject-matter for further investigation; and in reference to the latter part of the paper, *viz.*, that dealing with the analytical examination of these residual solutions, considering how complex these solutions often are, I think absolute accuracy in the determinations of all the constituents can hardly be looked for, except perhaps by the employment of long and tedious processes. The above scheme of examination only aims at allowing of the composition of such solutions being determined with a fair degree of accuracy, more or less expeditiously, and I trust it may at least prove of some little use to chemists employed in the industry of gold extraction by the cyanide process.

#### DISCUSSION.

Mr. ALFRED JAMES remarked that some months since he had received a notice from the Executive of the Section calling for suggestions as to subjects for papers or for special investigation, and that he had at that time felt strongly inclined to suggest that special information as to the technical analysis of cyanide solutions was very urgently needed. He therefore deemed it a matter for special congratulation that the Society should have had such a paper presented to it as that to which they had just listened; the more so, as Mr. Ellis had been one of the earliest and foremost investigators into the theory and practice of extraction of gold by cyanide solutions, and had done a vast amount of work on the subject.

He had to confess, however, to a slight sense of disappointment, that whilst the author had given them some very interesting information as to the behaviour of the double cyanide of zinc and potassium in the presence of excess of caustic potash, and as to the similarity of the behaviour and reactions of this double cyanide to those of free cyanide of potassium, yet the paper did not supply any method for the determination of these two salts in the presence of each other.

This was a most important matter to the chemist in charge of a cyanide works. Unless he could tell how much of his nitrate of silver test was due to the free cyanide present, and how much to the double cyanide of zinc and potassium *plus* caustic potash, he had no means of knowing, beyond the actual weight of free cyanide added to the stock solutions, the amount of the latter actually present in his solutions. Mr. Ellis had shown them that the double

cyanide plus caustic potash would give extractions of fairly high percentage, though perhaps inferior to those obtained by the use of simple cyanide alone; and he thought there was no doubt that in general practice it was found that the double cyanide was less effective, owing perhaps to impurities in works solutions.

Of course, if the equation adopted by Bittel was actually correct, and—

then of course all the double cyanide was converted into free (or simple) cyanide, with the formation of oxide of zinc and potassium; but he was unable to accept this equation; for, although it had been proved that the double cyanide plus caustic potash (or soda) had a considerable action on gold, the regeneration theory was not necessary to account for this. One could expect that there would be some such action, as, if the silver in the  $AgNO_3$  had the power to displace zinc from the double cyanide of zinc and potassium, gold in the presence of free oxygen might have that power also; thus:—

To settle this point of "regeneration," if possible, he had made some experiments, and as direct analytical methods were inadmissible, owing to the similar behaviour of the two substances, he had tried the effect of dissolving molecular weights, as in the above first-mentioned equation, and crystallising out the product from the saturated solution.

As a result he had found that the solution formed had, on heating, not given out the slightest odour of  $HCy$ , so noticeable with cyanide solutions, and that the deposited crystals on being analysed were almost pure double cyanide of zinc and potassium ( $K_2ZnCy_4$ ), and that they contained almost all the  $Cy$  originally taken; and he was therefore confirmed in the conclusion that with saturated solutions, at any rate, double cyanide of zinc and potassium and caustic potash did not combine to form free cyanide of potassium.

Having, however, got thus far, he thought it might be of advantage to test the converse equation, and see if free cyanide of potassium and oxide of zinc and potassium combined to form the double cyanide and caustic potash:—

He accordingly took the molecular quantities shown in the above equation, but found some difficulty in forming the oxide of zinc and potassium, and had to use an excess of caustic potash. On crystallising out, however, he got all the zinc down as pure crystals of double cyanide of zinc and potassium; thus showing that, at least with saturated solutions and excess of cyanide of potassium, the latter is the correct equation, and that in place of free cyanide being formed by the combination of double zinc potassium cyanide and caustic potash, free cyanide actually combined with the oxide of zinc and potassium to form the double cyanide.

In conclusion, he ventured to hope Mr. Ellis might be induced to lay before the Society a further account of his investigations into this matter.

Mr. BELLBY asked if Mr. Ellis could tell to what extent the dissolved oxygen in dilute solutions was used up in the wasteful oxidation of cyanide.

The CHAIRMAN said he had recently seen it stated that the action of an aqueous solution of potassium cyanide on gold in presence of atmospheric oxygen really takes place in two stages, and that one of the products of the first reaction was hydrogen peroxide. It was also suggested that as hydrogen peroxide converts hydrogen cyanide into oxamide, this formation of the peroxide during the dissolution of the gold would account for part of the loss of cyanide during the process. This seemed a point of some interest, and he would be glad if Mr. Ellis could give any further information.

Mr. ELLIS said, in reply, that he quite agreed with Mr. James as to the want of a speedy and at the same time accurate method of determination of simple alkaline cyanide,

as distinct from double zinc cyanide, when both were present in solution along with caustic alkali. By the crystallisation experiments to which Mr. James had referred, he thought that the former had settled the point that, in strong solutions, zinc double cyanide and caustic alkali together did not react to form simple alkaline cyanide and zinc potassium oxide, and, in fact, that the converse did take place; this, however, seemed to be a reaction which might depend much on the degree of dilution of the mixed solution, &c.; but that in any case these experiments of his offered one more piece of evidence in favour of the view that this reaction probably did not take place.

In reply to Mr. Bellby's question, he stated that he had not yet made any series of experiments on the point.

In reply to Prof. Henderson's remarks, he said he was unaware whether or not hydric peroxide was formed in the solutions in the way stated; if so, it might of course react as suggested to form oxamide, or possibly also sulphocyanide, if any lead sulphide were also present, as pointed out by Bittel and Feldtmann in another connection. It might thus be one factor in the consumption or destruction of cyanide, though he hardly thought one of any great practical importance.

Hon. Local Secretary:

Meeting held on Friday, January 22nd, 1897.

MR. R. C. WOODCOCK IN THE CHAIR.

THE CHAIRMAN read the following letter from Dr. Edw. Schunck, F.R.S., President of the Society, to Dr. Chandler:—

"Dear Sir—

"As President of the Society of Chemical Industry, I may address you as Chairman of the New York Section of our Society without ceremony or any formal introduction. I wish you to be the vehicle of conveying to the members of your Section my sentiments of esteem and my best wishes for their happiness and prosperity during the year that is just commencing. I wish that during my Presidency it had been possible for me to cross the Atlantic and pay you a visit in New York; but at my age (I am now in my 77th year) this could not be. On the other hand, I shall be delighted to see you, and as many of the members of your Section as may find it convenient to come to our General Meeting next July in Manchester, where you and they will meet with a cordial reception. Please accept my best wishes for yourself individually, and believe me,

"Yours sincerely,

"EDWARD SCHUNCK."

## THE ANALYSIS AND CHEMISTRY OF ASPHALT.—II.

By H. ENDEMANN, Ph.D.

IN my previous communication upon the same subject, I have shown that the old methods of analysis of paving asphalts (see this Journal, xiv. 315, 524, 960, and xv. 222, 298) are at fault by not giving us a correct idea of their composition. I have shown further that these asphalts consist of a compound containing oxygen and a series of

inert hydrocarbons. For the first I have adopted Boussingault's name "asphaltene," for the reason that it is the main constituent of the asphalt, though Boussingault's asphaltene was a different body and really a product of oxidation formed only during the analysis and not pre-existing in asphalt. For the second I have also adopted Boussingault's name "petroleum," for the reason of identity.

While the asphaltene is a somewhat easily changed body and entirely non-volatile and hard and brittle in the cold, the petroleums were found to be comparatively stable compounds, volatile and liquid. They serve to soften the asphaltene and give it the desired elasticity, which makes asphalt so useful a material for paving purposes. I have also shown that the asphaltene of different asphalts has the same composition and identical properties, inasmuch as it will oxidise when heated in air to about 250° C. and form a body which is the same in all cases and evidently identical with Boussingault's mistaken asphaltene.

I have called this body, which I have since obtained from a series of other asphalts, "asphaltic acid," for the reason that I consider it the cause for the solubility of metallic oxides in chloroform, considering such solubility to be due to the formation of a salt. Its preparation is simple, and consists in heating asphalt bitumen or asphalt in air to a temperature of 250° C.

Asphaltene is at first liquid. It soon covers with a wrinkled skin, which has to be broken from time to time by stirring, to allow the air free access to the material. When the liquid has nearly all disappeared the mass becomes at 250° C. elastic like rubber, but soon after hard and brittle, and when repeatedly pulverised, hard and dry like sand. This is the stage when heating may be interrupted. Further heating will not change the product unless the temperature limit of 250° C. is grossly transgressed.

If this body is heated with caustic soda solution it dissolves, forming a deep brown liquid, which, on addition of an acid, gives a brown precipitate. This process of dissolving is an exceedingly slow one. Continued for weeks only a small portion of the material could be brought into the solution. Asphaltic acid I therefore had looked upon as an anhydride until the analysis of the body suggested another procedure for its preparation.

The analysis proved conclusively that the body was not the product of hydration only, but a product of oxidation. Hence the solution was effected thereafter by dissolving in soda solution, while a current of air was drawn through the solution. What could not be accomplished in weeks was then done in days.

The brown solutions obtained were precipitated by hydrochloric acid, the precipitate brought upon a filter and washed. For further purification it was re-dissolved in ammonia and re-precipitated, filtered, and washed.

The free acid is soluble in pure water, but insoluble in water containing salts. It is a strong acid, dissolving in ammonia with decided development of heat. The acid and salts are all dark brown.

Two elementary analyses were made of this body—(a) acid dried below 100° C.; (b) dried at 125° C.

	(a.)	(b.)	Calculated for $C_{26}H_{20}O_{12}$
Carbon.....	57.00	59.40	59.54
Hydrogen.....	4.27	3.86	3.82
Oxygen.....	38.54	36.74	36.64

The ammonia salt, evaporated until odour of excessive ammonia is no longer noticed and then precipitated by sulphate of copper, produces a copper salt containing 15.95 per cent. CuO.

If evaporation is continued until some free acid is formed, i.e., when the mass has become dry and the undissolved free acid thus formed has been removed by filtration of the water solution, the copper salt contains 12.0 per cent. CuO. Hence, one was perhaps a basic salt, while the other contained free acid. The free acid was then titrated

with  $\frac{1}{2}$  normal soda solution. The dark coloured solution prevented the use of an indicator in the solution. It had therefore to be neutralized by the use of litmus paper. But even then the colour of the solution interfered to such extent that it was not possible to get nearer to the point of neutralisation than about  $\frac{1}{25}$  of all the quantity of soda solution required. All that could be seen by this test was that the neutral reacting salt corresponded about to a copper salt containing 13.9 per cent. of oxide of copper (calculated).

The point of neutralisation had to be guessed at by determining the point of actual acidity and actual alkalinity and putting the point of actual neutralisation arbitrarily at the average. These salts are not well suited for determination of actual molecular weight.

I have called attention to the fact that the conversion of asphaltic acid to this new acid—which I will call asphaltulmic acid—by means of soda is a very tedious operation, and, in fact, I have never carried the reaction so far as to dissolve all asphaltic acid. The difference in composition—

$C_{26}H_{20}O_4$  for asphaltic acid, and

$C_{26}H_{20}O_{12}$  for asphaltulmic acid,

might suggest that the substance called asphaltic acid were a mixture of a substance containing but little oxygen and another very much richer. Though I was always able, no matter when the process was interrupted, to again bring new material into solution by continuing the treatment, showing thereby that the substance still had the same property, I considered it safer to determine the composition of the residue, and thus affirm my belief into the uniformity of the substance called asphaltic acid.

0.1578 gave 0.0984  $H_2O$  and 0.4484  $CO_2$ —

Carbon.....	77.50
Hydrogen.....	6.92
Oxygen.....	15.85

which is the composition of asphaltic acid. This fractional treatment is also one of the best proofs of the uniformity of this substance. In fact, it has so far been the only one, inasmuch as other proofs are hardly available. The substances have a high atomic weight. Crystallisation as a means of separation cannot be used, inasmuch as all salts are amorphous. The ammonia salt and other soluble salts dry like gums, so does the free asphaltulmic acid. The free acid is insoluble in alcohol.

Altogether the hope of using this compound for the purpose of revising the assumption giving to the formulae of these compounds 26 atoms of carbon had to be relinquished.

*Soft and Liquid Asphalts or Malthas.*—It is a well-known fact that besides the more or less hard paving asphalts, liquid asphalts are found, which, with characteristic asphalt odour, nevertheless show properties not in keeping with the composition of those previously mentioned.

They are more or less liquid and contain but little oxygen, or, in some cases, none at all. To this class belong the malthas. The investigation made in this direction was carried out on a Texas liquid asphalt, which on examination had been found to be entirely free from oxygen. It was therefore free from asphaltene. When such heavy oils are evaporated, it is with great loss, for such will lose on refining to harden as much as 80 per cent. of oil before they really become as hard as consistency of asphalt for varnish manufacture, and then only when absorption of oxygen is possible. The loss in current of carbon dioxide is quick at first, slower later, but it lasts a long while. When the stage had been reached that a slow continuous loss at 250° C. is noticed, the residue was analysed. The residue was found to be  $C_{26}H_{36}$  with a varying but small quantity of oxygen. In two different treatments the following results were obtained:—

Carbon.....	87.77	86.89
Hydrogen.....	10.23	10.36
Oxygen.....	2.00	2.75

It is somewhat doubtful where in these cases the oxygen came from, inasmuch as the bitumen from which they had

been obtained was entirely free from oxygen. For instance, 0.1812 gave 0.1821 water and 0.5919 carbon dioxide.

Carbon .....	89.07
Hydrogen .....	11.16

Other analyses gave a like result.

Either the commercial carbon dioxide had contained oxygen or this hydrocarbon is capable of decomposing  $\text{CO}_2$  at  $250^\circ\text{C}$ .

The former is the more probable, however. So low a percentage as 0.05 per cent. of oxygen, which is considered sufficient for causing the change is not easily found in carbon dioxide gas by an ordinary test, such as I have had occasion to make quite frequently.

I have not investigated this point as yet, inasmuch as it would have led me from the subject-matter of this investigation, which in the first place meant the establishment of a safe and rational method of analysis.

Inasmuch as the absorption of oxygen may have been preceded by a loss of hydrogen, I prepared this body on a different plan. I distilled the petroleums from a larger quantity of asphalt in the vacuum. I then extracted the residue in the retort repeatedly with much boiling alcohol. The remainder was dissolved in ether, the ether removed and residue analysed.

0.1948 gave 0.1928  $\text{H}_2\text{O}$  and 0.6363  $\text{CO}_2$ —

Carbon .....	89.08
Hydrogen .....	11.00

calculated for  $\text{C}_{26}\text{H}_{38}$ .

Carbon .....	89.11
Hydrogen .....	10.89

The substance is a gum, entirely inodorous and in colour much lighter than asphaltene.

If we heat the asphalt bitumen of such asphalts in air, we find that they first lose rapidly in weight on account of the loss of petroleum, and that later on they gain in weight.

4.635 grms. after seven hours' heating in air-bath to  $250^\circ\text{C}$ . yielded 3.070, and after nine hours' further heating, 3.440 grms.

The liquid after the first rapid evaporation became covered with a skin, which, when pushed aside, gradually agglomerated to an elastic mass, and finally became hard and brittle.

The substance which was left behind was found to be asphaltic acid.

0.1739 gave 0.0982 water and 0.498 carbon dioxide—

Carbon .....	78.00
Hydrogen .....	6.27
Oxygen .....	15.74

It could be converted into asphaltulmic acid by soda solution.

This shows that these asphalts contain a hydrocarbon  $\text{C}_{26}\text{H}_{38}$ , which is capable by oxidation to pass into asphaltene and asphaltic acid; and furthermore, that this substance possesses a great affinity to oxygen, inasmuch as it will take it from such commercial carbon dioxide directly as will not pass any oxygen to asphaltene. I call this hydrocarbon "asphaltogen." Asphaltogen must be looked upon as an asphaltene preservative, in so far that as long as it is present the oxidation of asphaltene to asphaltic acid can be prevented.

This asphaltogen is a somewhat volatile hydrocarbon. Bitumens free from it will oxidise at  $250^\circ\text{C}$ . in a porcelain dish without discoloring the porcelain, except where the liquid comes in contact with it. If asphaltogen is contained in bitumen, the porcelain dish becomes coated above the surface of the liquid with a black mass of asphaltic acid. This behaviour may be looked upon as a test of the presence of asphaltogen.

It can thus be shown that the petroleum residuum oils contain asphaltogen (25 per cent.). (See this Journal, 1896, XV. 267).

Asphaltogen is solid at ordinary temperature, but melts already in the water-bath. It is soluble in ether, wherein asphaltene is insoluble.

**Analysis of Soft Asphalts.**—To determine asphaltogen in presence of asphaltene we may proceed as follows:—

Keep the bitumen for a considerable time at a temperature of about, but below,  $200^\circ\text{C}$ . At this temperature but little asphaltogen will evaporate, but it will readily pass

into asphaltene. Then raise the temperature and convert into asphaltic acid. Thus we obtain the asphaltic acid obtained from asphaltogen as well as from asphaltene.

Determine then the quantity of oxygen in the untreated bitumen, and calculate therefrom the asphaltene present ( $8.12$  per cent. =  $100$  asphaltene).  $38.0$  asphaltene yield  $402$  asphaltic acid.

The whole asphaltic acid—

- = Asphaltic acid from asphaltene
- = Asphaltic acid from asphaltogen
- $402$  Asphaltic acid =  $350$  asphaltogen.

Then bitumen—

- = (Asphaltene + asphaltogen)
- = Petroleum.

**Review and Conclusions.**—The formulæ of the substances, which have been described in this paper may require revision, inasmuch as I have so far not been able to obtain any compound which could be used for an accurate determination of molecular weights. Yet for practical purposes they will be found accurate enough for calculation of results. The substances described are—

Asphaltogen.....	$\text{C}_{26}\text{H}_{38}$	} $\text{C}_{26}\text{H}_{38}\text{O}_2$ ( $\text{CO}_2\text{H}$ )
+ Asphaltene.....	$\text{C}_{26}\text{H}_{38}\text{O}_2$	
Asphaltic acid.....	$\text{C}_{26}\text{H}_{38}\text{O}_4$	
Asphaltulmic acid.....	$\text{C}_{26}\text{H}_{38}\text{O}_{12}$	
+ Melting point $210^\circ\text{C}$ .		

The first two are the useful constituents of natural asphalt: the latter two are products of oxidation of the first and not found in natural asphalts, except perhaps as products of accidental degeneration. Asphaltogen absorbs oxygen at elevated temperature with great avidity; asphaltene absorbs oxygen likewise, but not so easily. Crude asphalts containing asphaltogen may be oxidised so that they will contain asphaltene. Asphalts containing both will, by heating in air, become poorer in asphaltogen and richer in asphaltene. Asphaltene will oxidise only after the asphaltogen has been oxidised, the latter will therefore wield a protective influence upon the former. In smelting asphalt for the preparation of asphalt cement and for softening, oils containing asphaltogen should be added. Such oils are the malthas or petroleum residuum oil. The former are to be preferred on account of the nature of the petroleums, i.e., the oils which will soften the asphaltene.

If we mix and heat asphaltic acid with petroleum residuum oil, or with petroleum from asphaltum, we obtain mixtures like sand and water.

If we mix and heat asphaltene with petroleum residuum oil, we obtain a somewhat plastic mixture.

If we mix and heat asphaltene with maltha petroleums, we obtain a real asphalt.

This leads us to the consideration of the composition and nature of the substances which we call petroleum.

The hydrocarbons of petroleum residuum oils are to a large extent paraffins. But petroleum residuum oils form with asphaltene not advantageous mixtures; hence we must conclude that the petroleums of asphalt cannot be paraffins—at least not predominantly.

Asphaltogen is a hydrocarbon of the general formula  $\text{C}_n\text{H}_{2n-14}$ .

From the analyses which I have made we can conclude that the petroleum hydrocarbons must contain more H than is contained in the easily oxidisable asphaltogen.

The indications derived from physical properties and chemical tests are for hydrocarbons of the general formula  $\text{C}_n\text{H}_{2n-4}$ , with perhaps others containing more hydrogen and nearing more and more the paraffins ( $\text{C}_n\text{H}_{2n+2}$ ). To determine the series to which these hydrocarbons belong an elementary analysis of the substances is not sufficient, but will have to be supplemented by determinations of the vapour densities of the carefully purified products.

The liquid asphalts are best suited for the separation of the petroleums, for the reason that they are richest. There is, however, a possibility that the petroleums contain some asphaltogen, though the boiling points of asphaltogen and

\* This method is applicable for the analysis of paving asphalts.

the petroleues are far apart. In order to obtain them from Texas asphalt we proceed as follows:—

At first the water is driven out in an open casserole. Asphalt containing water foams to such an extent that it is hardly safe to undertake the boiling in a vessel more than a quarter filled. With the water some petroleues are lost. When the foaming ceased 9 per cent. had been lost. The liquid mass is now filled into a retort, and carefully distilled over the naked flame under a partial (half) vacuum. The distillation, at first quite brisk, all at once stops, when the asphaltogen remains in the retort. Thus about 27 per cent. petroleues could be collected. To learn something about their nature they were distilled under ordinary pressure with thermometer. Evenly with the time, the thermometer rose. Commencing from about 260° C. to 320° C. about one-third had passed over. The lower petroleues possess a very strong asphalt odour. The higher petroleues are almost odourless, unless rubbed between the hands, when they also develop the same odour, but much weaker.

The higher petroleues were not distilled, for the reason that the thermometer commenced to work irregularly. I, however, had been learned, namely, that what we call petroleum is a complicated mixture. It contains a series of compounds, perhaps not even all belonging to a single of the aliphatic series, but comprising representatives of several such.

I have to leave this subject for a later communication, as likewise the relation of some petroleum compounds to asphaltogen, and the occurrence of nitrogenous and sulphur compounds with the petroleues.

*Remarks on Analysis of Paving Asphalts.*—In my first paper I have shown that asphaltene is soluble in a petroleum ether solution of petroleum. Asphaltic acid in combination with bases is soluble in a chloroform solution of asphaltene. It is more soluble in a concentrated solution than in a dilute solution. We meet, therefore, also here the mistaken observation that “the fine silts will pass through the filter,” only that in this case not only organic matter but really mineral matter will be found in the sediment. If this sediment be kept by itself and is examined, asphaltic acid, and from this asphaltulmic acid, may be separated and produced.

Much of the organic matter—not bitumen—found in refined asphalts is asphaltic acid in combination with the mineral matter. In the determination of total bitumen in paving asphalts it is indicated to decant or filter from any precipitate which may be produced by the addition of the chloroform washings to the first chloroform extract, inasmuch as the asphaltic acid and its compounds can no longer, and should not be, counted with the bitumen.

After concentrating the extract, and for the purpose of driving off the last traces of chloroform, we heat in an air-bath for a certain time (see this Journal, 1896, 874). I wish to add here that it is advisable to lay the flask containing the extract sideways, for the purpose of aiding the escape of the heavy chloroform vapours, especially if one desires to effect the escape of the chloroform within the prescribed time.

*Practical Application of Analytical Results.*—I have shown that in the analysis of asphalts by the old method, using petroleum ether as a solvent for the petroleum, not only the petroleum but a far greater quantity of asphaltene goes into the solution. In the case of the analysis of the Mexican asphalt it has been seen that this so-called petroleum consists of—

26.51 petroleum, and  
69.61 asphaltene.

All liquid asphalts containing petroleum and asphaltene in this proportion, down to those which contain no asphaltene or asphaltogen at all, give by this method identical results. Hence such results cannot give us any hints as to the applicability of these more or less liquid asphalts for the production of compositions of standard properties and consistency, while the results of analyses made according to my plan can be applied at once. For instance, it is proposed to imitate the bitumen of refined Mexican paving asphalt containing—

71 asphaltene ..... } 98 bitumen;  
27 petroleum .....

by using Trinidad asphalt containing—

50 asphaltene ..... } 58 bitumen;  
8 petroleum .....

and a maltha containing—

56 asphaltene ..... } 94 bitumen;  
38 petroleum .....

then we find by a simple calculation that we have to mix these constituents in the following proportion:—

100 maltha,  
149 Trinidad asphalt,

and for the purpose of making of this cement a 15 per cent. paving mixture we require for—

1,600 cement,  
3,833 sand and limestone.

The correctness of the above calculations has been practically tested.

In working on a large scale, allowance must be made for oxidation of asphaltene and volatilisation of petroleum by the determination of a factory coefficient.

## DISCUSSION.

The CHAIRMAN said it was somewhat extraordinary, when one remembered that asphalt was undoubtedly used in the early days of the Egyptians, that the papers that Dr. Endemann had given them undoubtedly contained more chemistry and valuable information than all those that had been published before. If one searched through chemical journals, whether analytical or manufacturing, the knowledge one could obtain on this subject was very limited.

In Dr. Endemann's former paper all were struck by the statement that such very large quantities of mineral matter were extracted by chloroform; and he (the Chairman) took occasion to remark then that he thought it was most likely that the whole of this mineral matter must be in organic combination; and Dr. Endemann now stated that this chloroform-extracted mineral matter was probably combined with asphaltic acid. If he remembered correctly, Dr. Endemann stated in his previous paper that the chloroform was used directly on the crude asphalt as a means of extracting certain products, and with that chloroform extract he got these large quantities of mineral matter. Now, Dr. Endemann told them that this asphaltic oxide was only produced after the asphalt had become oxidised, and that it was not contained in any considerable quantity in the original asphalt. If such were the case, therefore, how was it that the original asphalt gave so much mineral matter in its chloroform extract? Dr. Endemann stated that this asphaltic oxide was not very soluble in chloroform. If this oxide (or acid, as he also termed it), when combined with mineral matter, dissolved to a large extent in chloroform, it seemed very extraordinary that the oxide, which was probably free anhydrous acid, should not dissolve in the chloroform to any considerable extent. There was one other question he would like to ask, and that was whether the asphalts that the author had been examining as they arrived at the present day contained any considerable quantity of arsenic?

MR. CLIFFORD RICHARDSON said Dr. Endemann seemed to have neglected a very important element in the asphalts—the amount of sulphur present.

DR. W. J. SCHIEFFELIN asked whether Dr. Endemann had proved his process of analysis on any mixture made up of known quantities of the different ingredients to which he had alluded.

MR. CLIFFORD RICHARDSON said he had noticed in the last number of the Journal of the Society, in a paper by Dr. Endemann, at the reading of which he was unable to be present, that he gave an analysis of petroleum and asphaltene, so called, in which he included quite a large amount of oxygen. He (Mr. Richardson) was unaware that there was any oxygen in these substances, and he did not understand how Dr. Endemann found that there was any there. What were known as petroleum and asphaltene in the technical sense in which he first introduced the terms some seven or eight years ago, were substances obtained by the use

of different solvents on asphalt, the determination of which was convenient merely as denoting, from the relative amount of each found, the character of different asphalts, in exactly the same way that persons dealing in crude petroleum denoted its character by the relative amount of gasoline, burning and lubricating oils which could be obtained from it by distillation. Petroleum was distinguished in this way. They must also have some way of distinguishing asphalt technically, and they found it convenient and accurate to do so by determining the relative amounts soluble in naphtha and in carbon bisulphide or chloroform. There was no claim at all that there was any sharp separation of hydrocarbons by these solvents. It was only a technical one. A certain amount of the higher hydrocarbons, which they had called asphaltene, might go into solution in the naphtha, and a certain amount of the lower hydrocarbons might remain in the chloroform. The method was of analytical accuracy, and of value in the comparison of the properties of different asphalts. If they analysed the hydrocarbons petroleum and asphaltene, making an ultimate combustion, they found that they consisted of a certain amount of carbon and hydrogen in each case, but that the percentages of the two did not add up to 100. Carrying the examination still further, they found that in the petroleum, that is, in the hydrocarbons soluble in naphtha, there was about 3.8 per cent. of sulphur. Now, if that percentage of sulphur were added to that of the carbon and hydrogen it would bring the analysis up to 100—at all events in the case of Trinidad asphalt. In the same way with the hydrocarbons extracted with chloroform, after previous extraction with naphtha: if they determined carbon and hydrogen in them, they found that the percentages added up to even less than that obtained in the case of petroleum. That is to say, there would be a lack of as much as 10 per cent. from a total of 100. But the sulphur in these hydrocarbons also served to make up the necessary 10 per cent.

This was one of the most important features in connection with the hydrocarbons of asphalt. There were no asphalts anywhere, so far as he knew, which contained no sulphur, and as far as his experience had gone, none of the bitumens contained oxygen. Trinidad asphalt as refined, however, contained oxygen in the organic matter which was insoluble, and not of a bituminous nature. Sulphur was a very important thing in the presence of hydrocarbons, because of its relation to one of the interesting reactions of organic chemistry. If they heated with sulphur two molecules of a hydrocarbon—diphenylmethane, for instance,—two atoms of hydrogen were removed in combination with the sulphur to form hydrogen sulphide, and at the same time the two atoms of diphenylmethane united, or were condensed to form tetraphenylethylene. This reaction was well illustrated in the preparation of an artificial asphalt called "Pittsburg flux." It was made from the "residuum" of petroleum by heating it with sulphur. The sulphur removed some of the hydrogen atoms in the paraffin and olefine hydrocarbons, hydrogen sulphide was evolved, and the "residuum" was transformed into a substance of an asphalt type. The presence of sulphur was therefore a very important element in the case which was under consideration, and he thought that Dr. Endemann had neglected one of the essential features of the chemistry of asphalt. He would be glad to know if the author got his oxygen, in his analyses of petroleum and asphaltene, merely by difference. In the case of Trinidad and Bermudez asphalt, the bitumens contained no oxygens, but rather sulphur.

When they came to consider what petroleum and asphaltene were, they were not such mysteries after all. The petroleum of Ohio and Pennsylvania, as investigated by Mabery, consisted of hydrocarbons of the paraffin and the olefine series. They knew also, from the elaborate work of the Russian chemists, that the hydrocarbons of Russian petroleum were largely of the hexahydrobenzol series. It was with the asphalts exactly as it was with the petroleum; they must separate the hydrocarbons and sulphur derivatives in them, and determine what the series of hydrocarbons was to which they belonged. Asphalt was really nothing but another series of hydrocarbons, just like petroleum. In fact it was a petroleum in the widest

sense of the word, since petroleum and asphalt merged into one another by gradual gradation.

Recent investigations which he had carried on showed that the most volatile hydrocarbon extracted by naphtha from Trinidad asphalt was probably one of the members of the hexahydrobenzol series. The first thing that attracted attention in obtaining the lighter oils from asphalt was that they had an enormously high specific gravity for their molecular weight. They could determine their molecular weight by the boiling or freezing point method, and could also control it by the density and index of refraction of the substance, according to the methods of Bruhl and Traube. This physical determination, which Dr. Endemann seemed to have neglected, showed at once that the lower members, at least, of the series of asphaltic hydrocarbons contained a closed ring, and that they were probably higher members of the hexahydrobenzol series, or something more complicated. There was no reason, then, why they should not continue the investigation in the same manner from this point through the higher members of the series of asphalt hydrocarbons and their sulphur derivatives. There was no necessity for all these empirical formulae which Dr. Endemann had given, and which seemed to have very slight foundation upon a scientific basis. There were other methods for investigating asphalt, of a more scientific nature.

Dr. ENDEMANN said, in reply, that the asphaltic acid was mainly produced during the refining process by either faulty treatment or unavoidable oxidation from asphaltene. The asphaltic acid might, in the presence of bases, saturate itself, for there was generally more or less inorganic matter present. He should not be surprised if asphaltic acid went into the solution of asphaltene in chloroform likewise, just the same as in combination with bases. He had not investigated this point, nor that of the amount of arsenic found.

There were two substances which he had mentioned in his paper—the sulphur and the nitrogen. Neither sulphur nor nitrogen were contained in the asphaltogen and asphaltene. He had especially stated in his paper that they pertained to volatile substances, and the nitrogenous bodies and sulphur compounds which had been obtained by himself and others were found with the petroleum, and had not been investigated. He would investigate these substances hereafter.

As far as the names of petroleum and asphaltene were concerned, he thought that Boussingault, though long dead, had, so to say, a kind of a trade mark on them. Boussingault was the first to introduce them and describe them, and consequently, if anyone used the same names, he should use them as expressing the same things which the original inventor described; or, if one did not use them in the same sense as just explained, he should state why he did not use them in the original sense. In his (Dr. Endemann's) paper, he had stated that Boussingault had assumed the body asphaltic acid to be asphaltene, because he obtained it by heating the asphalt in air for a long period, but he really had not discovered asphaltene.

He adopted this name for real asphaltene, because he believed that Boussingault meant to call this body asphaltene. In the method of analysis which Mr. Richardson had introduced, there was absolutely no connection between the two substances.

In introducing this analysis by means of solvents, which he had proved in his paper to be absolutely incorrect and misleading, inasmuch as petroleum ether dissolved not only the petroleum, but likewise the asphaltene, Mr. Richardson's claim that this method, stated to be made up according to the plan by which petroleum oils were analysed, was absolutely incorrect and wrong, because using solvents was an entirely different thing from distillation. He (the author) had gone back to that original method of distillation, which was the one used in the examination of petroleum oils. Mr. Richardson had used an entirely new method, and now he likened his method to that which he (the author) had introduced.

In regard to the determination of the oxygen, the oxygen was determined by difference, after being ascertained that there was no sulphur present. Sulphur was in the distilled

be built (from cellar to roof) to divide it practically into separate buildings. Danger of damage by water is reduced to a minimum by having the floors watertight and graded to ample flush vents, and with the sills of the doors raised 3 ins.

A manufacturing laboratory requires large spaces for tanks and apparatus, with few columns to interfere with placing the same, and ample facilities for communication, such as elevators, dumb-waiters, schutes, speaking-tubes, and a variety of piping for conveying steam, compressed air, gases, and liquids. To comply with the fireproof requirements and yet not interfere with the essentials just mentioned, was the problem which we undertook to solve in 1894, when it became necessary for the firm of which I am a member to build a new laboratory, because the land on which our old laboratory stood had been taken by the City of New York to be made a public park. Thirty thousand square feet of room were required, and the system of construction selected is known as the Hecla fireproof construction. It consists of heavy steel columns supporting wide arches of concrete made from Portland cement. The concrete is cast in triangle forms between steel cantilevers and beams which extend between the columns, as per diagram, the beams are supported by curved brackets which, by virtue of the cantilever principle, allow a far wider span for a given weight of metal than does the ordinary rectangular fireproof construction; the spans in our laboratory are 30 ft., so that a room 50 ft.  $\times$  60 ft. has but one column. The floors have about 8 lb. of steel to the square foot, as compared to about 15 lb. for a like span of the usual rectangular construction.

The plan adopted is that of having three buildings around a courtyard, the largest building being divided by a continuous fireproof partition from the ground to the roof, thus substantially making the laboratory comprise four separate buildings under one roof, each building having three stories and a high cellar or basement with large windows. This arrangement of the plan admitted placing the stairways, elevator, dumb-waiter, and schutes outside the three manufacturing buildings, while they are all connected together, and direct communication with each other secured by means of the fourth building, which contains the boilers and drying rooms.

The building has a skeleton steel frame with skeleton cantilever steel floor construction filled in with concrete. The steel arches are grouped in triangles, the truss-beams transferring the loads immediately to the columns so that no intermediary system of girder and beam construction is required, thus economising steel and distributing the load evenly.

The work of putting in the floors took but a short time, and they were given six weeks time to set before heavy weights were put upon them. The fire partition from the ground to the roof in the large building is of rock plaster on expanded metal. It is 3 ins. thick and very strong. The other partitions are of rock plaster on jute bagging, they are 2 ins. thick and very rigid. The columns are protected from fire by being wrapped with  $\frac{1}{2}$  in. thick asbestos paper and then with heavy wire laths, which in turn was covered with about  $2\frac{1}{2}$  ins. of mortar composed of sand and lime, heavily gauged with plaster, and the floor beams being embedded in concrete and plaster are likewise protected. There are no hollow spaces between the floors and ceilings and the concrete becomes so firm that the floors are virtually on arches of artificial rock which would doubtless bear immense weight without the aid of the steel trusses. The specifications demanded that the floors support 250 lb. per square foot, but the actual strength is probably many times this amount. The floors are graded to flush outlets one to every 750 sq. ft., and the iron door sills are raised 3 ins. above the floor with inclined sides to facilitate the passing of trucks.

The doors are more fire resistant than those made of heavy iron, and are built according to specifications approved by the New York Board of Fire Underwriters, as follows:—Two thicknesses of 1-in. narrow-tongued and grooved, soft white pine boards, laid diagonally (both sides) and nailed with wrought nails driven through and clinched, then covered on both sides and edges with 10  $\times$  14 sheets of

"bright L.C." tin, joints flat-locked and securely nailed under laps (barbed wire nails used,  $\frac{1}{2}$  in. in size, driven 2 ins. apart), but not soldered. All doors lap 3 ins. over openings, except where doors close in jambs or angle iron framework. The doors are arranged to close automatically in case of fire: they are sliding doors hung with heavy wrought-iron hangers and sheaves firmly bolted to and through the doors by carriage bolts. The runway or track is placed at an incline of  $\frac{1}{2}$  in. to the foot and at such height that the doors when closed rest firmly on the raised sills. The doors are counterpoised by adjustable weights, hung on heavy sash cord in which is inserted over the centre of the door opening, a fusible link composed of two brass plates with rings for fastening, soldered together by the following alloy:—50 parts bismuth, 25 parts lead, 12 parts tin, and 13 cadmium. The melting point claimed is 68° C., but the one tested in the melting point apparatus of Roth melted at 78° C., which is probably low enough.

All the window frames are made of cast-iron. It is vital that windows opening on a courtyard should be fireproof, so that flames cannot be communicated from the outside; to attain this and avoid the trouble of fire shutters, the wire glass window panes were inserted: these are  $\frac{1}{2}$  in. thick, and the wire mesh is in the centre of the glass, which is fused around it. The glass may be heated to a red heat on one side, and then cold water played upon the other without its breaking from the frame: it will crack in all directions, but none fall out, being held together by the wire; moreover, a brick can be thrown violently against it while hot or cold and fail to break through.

To avoid holes in the floors the following means were adopted:—The plumbing and gas pipes were put in place before the concrete, and collars extending 3 ins. above the floor were placed where steam pipes were to be fitted, then the concrete was filled in around them. Power for the machinery in the upper floors is transmitted by electricity from a dynamo in the basement, along a main wire hung in the elevator shaft, to motors located wherever needed, thus abolishing the dust, noise, reverberation, loss of power, and danger from belting or vertical shafts. Where it was necessary to run the return cables for the larger elevator through the building, they were entirely encased in an extra heavy galvanised iron box.

There are three fire escapes, one of iron at the back of the large building, and two of stone and brick in corresponding turrets at the entrance to the courtyard: these are used as stairways, and have fire-doors opening to the centre on each floor and windows to allow the escape of smoke. To subdue any interior fire in its incipency, fire-hose, with high-water pressure, is placed at every stair landing outside the doors of the working rooms, and carbon dioxide extinguishers are at hand in every department.

In the smaller building, where the more inflammable materials are used in manufacture, the precaution has been taken to avoid any possible ignition from electric sparks by encasing the incandescent light sockets in rubber sleeves, and arranging them so that the current must be turned from a switch in the adjoining building, and motive power is supplied by steam engine instead of electric motor.

The composition of the surface of the floors varies with character of the materials used in the work: where they are dry, the floors are of concrete, sized with boiled linseed oil to prevent dust, and in the analytical department the floor is painted with two coats of oil-paint to make it absolutely dust proof. In a room where much petroleum is used as a solvent, the floor is covered with galvanised iron with soldered joints. Wherever water is apt to be spilt the floors are asphalt. The acid room has a floor of blue stone flag laid in tar and graded to an earthenware gutter and drain pipe.

The one disadvantage of the arched ceilings is the difficulty in hanging shafting, but by bolting wooden blocks to the cantilevers the hangers were adjusted.

The walls of the building are curtain walls, that is, enclosing walls sustaining only their own weight, and capable of being removed without disturbing the structure. There are flues built at intervals in the walls, and the main chimney from the boilers is outside the wall. The street walls are of washed brick trimmed with marble and buff.

brick and lined with hollow brick. The windows are on all sides of the building, so that the lighting and ventilation is excellent.

The cost of this system of fireproof construction depends on the price of steel and the skill and experience of the workmen who fill in the floor arches (much less time was required to construct the last of the floors put in than the first one). The cost is probably one-third more than ordinary wooden-mill construction, and one-fifth less than the rectangular beam and girder fireproof construction.

A marked advantage of this system is the stability of the structure, heavy machinery making but very slight vibration, and as the floors are braced in every direction and have windbraces in all the angles—like the knees of a ship—it would be useful in countries where earthquakes are prevalent. We have now occupied the building for 20 months, and it has proved satisfactory in every respect. The New York Board of Fire Underwriters has approved the building, and the Insurance Tariff Association has made a special rate upon it, which is one-third of what would be probable in ordinary construction, and is reported as the lowest rate on a laboratory in America.

#### DISCUSSION.

Mr. CHAS. M. REUBENS asked of what material the tops of the tables of the laboratory were constructed.

Dr. W. J. SCHIEFFELIN replied that they had different tops for different purposes. The word laboratory would probably convey to most of their minds the place where analytical and experimental work was done. Only one department of the building was used for that, and the rest for manufacturing—and a druggist had to manufacture a hundred and one different things. In the room in the research department where the physical work was done, and where the different balances, the microscope, polariscope, and different instruments were placed, the table top for the dry work was made of plate glass, about 30 ft. or 40 ft. long, running around the different sides of the room. The plate glass was set on green baize, and it made a very clean surface to work upon. In the analytical room the table was covered with soap-stone, albalene they called it, and it answered the purpose very well. Most soapstones, if butter or fat were dropped on them, would absorb them and stay dirty, but this did not, and one could scrape them off with a spatula. Soap-stone was better than slate, for if one put a beaker down a little harder than one intended, it did not break as easily as upon slate.

The middle table of the analytical room was used solely for inflammable substances, when they were making experiments with naphtha, kerosene, ether, alcohol, or chloroform, and the rule was that these were to be made on that table. Generally they used the steam water-bath in the corner for heating. If that were not heat enough they could arrange to have an electric heater, so that these fluids were never where there was any fire. The top of that table was soaked in paraffin. It was a soft pine table, and he had a tailor's goose heated by electricity, and put shavings of paraffin upon the table, and, heating the goose, rubbed it around until the paraffin soaked in. But it was not very satisfactory. It collected the dust, and although it did not absorb water and turned most of the solvents that dropped on it, he would prefer the clean wood.

The one on the other side of the room was arranged in the same way. The sink was made as waterproof as possible by taking cherry wood and heating it in a kiln at the cabinet-makers, who put in all the woodwork in this department. All the cabinet woodwork was of oak. He had a drying kiln, and the specifications were that the sink should be made of cherry and the drip board also heated in the kiln with paraffin, so that the wood should absorb it. It was done twice and water did not affect it very much. The inside of the sink was caulked with white lead, and it made a rather nicer sink than the old lead one, because that was apt to get black and rub off.

## I.—PLANT, APPARATUS, AND MACHINERY.

*Iron, Corrosion of, by Water containing Carbonic Acid.*  
P. Petit. Comptes rend. 1896, 123, 1278.

THE waters of the Moselle, which are only slightly calcareous, act energetically on iron, sometimes piercing the iron pipes or reservoirs, to which they have access. A moderate addition of lime to the water causes deposition of a protecting crust of calcium carbonate on the iron surfaces. The iron is dissolved as ferrous carbonate, which decomposes in contact with air, forming ferric oxide and carbonic acid, which latter continues the attack. Thus a very small proportion of carbonic acid dissolved in water, is capable of great mischief.

The action on iron of very dilute solutions of calcium chloride, sodium chloride, potassium sulphate, and calcium nitrate, with and without carbonic acid, as compared with pure water, was also studied. In absence of CO<sub>2</sub>, minute traces of iron were dissolved, though some was oxidised, sodium chloride and potassium sulphate acting most strongly. In presence of CO<sub>2</sub>, iron was in each case dissolved—most in the potassium sulphate solution, and least in that of calcium nitrate. In closed vessels, the iron oxidised was about the same with or without carbonic acid; but with access of air, the oxidation proceeded very rapidly, and especially in a solution of calcium chloride.

—E. S.

*Spectacles, New Protective.* Chem. Ind. 1896, 19, 554.

Dr. THOMAS, of Berlin, recommends the use of Schering's gelatoid in place of the wire-netting and glass at present used in spectacle construction. This gelatoid, specially hardened in amyl acetate, forms an elastic, solid, and perfectly transparent substance. The gelatoid pieces, serving as spectacle glasses, are perforated to allow passage of air to the eyes, whilst holes are also made in the side covers for the same purpose. The chief advantage in using gelatoid is that it is practically unbreakable, and, like horn, merely bends when struck by a foreign body, in cases where, under similar conditions, glass would splinter and perhaps cause injury.

\* Any of these specifications may be obtained by post by remitting 8d.—the price now fixed for all specifications, postage included—to Sir Henry Rader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

The gelatoid is made in all colours; it is not combustible, merely carbonising when heated; and lenses made with it do not cloud over when the wearer passes from a cold to a warm atmosphere.—J. T. C.

#### PATENTS.

*Evaporators, Impts. in and relating to the Discharging of Salts and the like from.* J. Foster, Pollokshields, Glasgow. Eng. Pat. 928, Jan. 14, 1896.

THE salts, &c., are withdrawn through a discharge valve in the lower end of the evaporator, into a pump barrel, and are delivered through a second valve in the barrel on the return stroke of the pump piston, the claim being for "the combination of a discharge valve at the lower end of an evaporator, working in time unison with an outlet valve in the pump barrel."—R. A.

*Furnaces, Impts. in.* [Generator Furnace.] W. P. Thompson, Manchester. From M. Herwig, Hesse-Nassau. Eng. Pat. 22,427, Oct. 9, 1896.

A GENERATOR-FURNACE having an "air superheater so constructed in the furnace that the outer wall of the latter forms also one outside wall of the air superheater, and the opposite wall of the latter encloses or limits the fire chamber, and is provided with discharge openings for branch flames derived from the generator furnace." The fourth claim is for "a form of construction of the generator furnace, in which the air superheater is extended round the entire wall of the furnace, and having, with the latter, its mouth at the top in the form of a tube-shaped extension. Thus, a most thorough utilisation of the radiated heat of the furnace," is said to be attained.—A. S.

## II.—FUEL, GAS, AND LIGHT.

*Peat, Production of Artificial Coal from.* Glückauf, 1896, 32, 923.

OWING to the low calorific value of peat in comparison with its bulk, and to the large percentage of ash, the cost of transporting it is prohibitive. Many attempts have therefore been made to convert it into coke. The largest bores occur in Norway, and there Angel has carbonised peat by heating it to 250°–300° in open retorts for 10 hours, by which process gases, steam, and tarry constituents escaped and 50 per cent. of coke remained; but the method was too expensive. Rosendahl has now placed the matter on a practical footing. The peat is heated in closed iron retorts provided with a cock; the temperature is gradually raised to 250° C., and the cock, which is at first left open, is then closed, and the material kept at this temperature for seven hours. The result is that tar and gaseous products remain in the carbonised mass, and the yield of the artificial fuel thus produced, amounts to 80 per cent. of the peat employed. The analysis of the latter shows C = 65 per cent., O = 16 per cent., H = 6 per cent., H<sub>2</sub>O = 3.7 per cent., and ash = 5 per cent. The artificial peat-coal has a calorific power of 6,500 cal., which, it is said, is nearly equal to that of ordinary coal. 1,000 kilos. can be sold at M. 7. Experiments at Krupp's works have shown that the material may be satisfactorily used in the iron foundry.—W. G. M.

*Thorium, The Sources of.* Rev. Chim. Ind. 7, [84], 372–374.

THE Norwegian minerals *thorite* and *orangite* contain a minimum of 20 per cent. of thorium, and their price is about 6s. to 8s. per kilo. per unit of thorium. Monazite is now the chief source of thorium, and, being found in large quantities, it has caused a reduction in price of pure ThO<sub>2</sub> from 240 dols. to about 36 dols. per lb. A few months ago the consuls of the United States were directed to report upon the trade in monazite, and the following is an abstract of their reports.

Monazite is a phosphate of cerium and lanthanum, containing small quantities of didymium and thorium; but the thorium is the valuable constituent, as it is used in the manufacture of incandescent mantles. The specific gravity of the mineral is 4.9 to 5.3, and it varies in colour from yellow to brownish-grey. It occurs in North America (in

North and South Carolina, Quebec, and Connecticut), Brazil, and Russia. In North America the larger crystals of monazite are picked up by hand, but the sand is washed with water, as in the treatment of auriferous sands, yielding a product containing the monazite and particles of magnetite, ilmenite, garnets, and other impurities. After drying, the magnetite (but not the ilmenite) is removed with magnets. The sand then contains about 50 to 60 per cent. of monazite, and is sold at 25 to 30 cents per lb. The pure monazite crystals are worth 50 to 60 cents per lb. The Brazilian sand is found at Antigua, Bahia, Minas Geraes, Caravelas, and San Pedro, and is loaded directly into the ships, the cost amounting merely to that of the labour. In other districts—at the diamond mines of Rio Chico, Villa Bella, Cuyaba, and Goyaz—it is found as rounded nodules speckled with orangite. The following table shows the amount of rare earths in average samples of the well-washed mineral:—

	Oxide of Thorium.	Oxides of the Cerium Group.	Oxides of the Yttrium Group.
Quebec .....	1.10	50.2	4.5
Connecticut .....	1.40	61.0	..
North and South Carolina ..	0.23–0.80	39–63.3	0.1
Bahia .....	1.20	33.0	1.2
Minas Geraes .....	2.40	51.0	2.2
Rio Chico .....	4.80	53.0	3.2
Villa Bella .....	5.30	62.4	4.4
Goyaz .....	7.60	64.1	5.1

The price of monazite in the first shipments from Brazil, was quoted at 85l. per ton, but last winter it had fallen to 15l. per ton. Really the supply now exceeds the demand. Most of it is used at Vienna in manufacturing incandescent mantles.—H. B.

#### PATENTS.

*Cyanogen Compounds, Impts. in Methods of Separating from Gas Liquor or other Solutions.* H. Bower, Philadelphia, U.S.A. Eng. Pat. 361, Jan. 6, 1896.

IRON, or an iron salt, is added to ammoniacal liquor in sufficient proportion to form iron salts with the cyanogen compounds present. Lime is then added, and the ammonia is distilled off. The liquor, now containing calcium ferrocyanide and sulphocyanide, is treated with an acid solution of a copper salt, preferably cuprous chloride. The precipitate, containing copper ferrocyanide and sulphocyanide, is separated, and heated in an autoclave under pressure with iron filings or reduced iron, when iron salts are formed with separation of copper, which decomposes the sulphocyanide with production of copper sulphide and iron ferrocyanide, the latter being now the only cyanogen compound present. From the iron ferrocyanide, alkali ferrocyanides are readily obtained. Reference is made to the inventor's previous Eng. Pat. 8330, 1895 (this Journal, 1896, 274).—E. S.

*Incandescent Gas Lighting, Impts. in the Manufacture of Mantles for.* W. Mackean and The Incandescent Gas Light Co., Ltd., Westminster. Eng. Pat. 3681, Feb. 18, 1896.

MANTLES are to be made by mixing oxides (either hydrated or anhydrous) or carbonates of suitable metals (*e.g.*, the rare earths) with a solution of an ammoniacal salt, such as the acetate, nitrate, or sulphate, impregnating a fabric with this mixture, drying the impregnated fabric, and burning off as usual.—H. B.

*Incandescence Bodies for Illuminating Purposes, Impts. in the Manufacture of.* W. Nicholls, London. Eng. Pat. 4000, Feb. 21, 1896.

MANTLES are to be made by impregnating suitable fabric in the usual manner with a solution of the following mixture of salts:—Zirconium nitrate, 55 parts; calcium nitrate, 45 parts; yttrium nitrate, 3 parts; uranium nitrate, 0.5 part.—H. B.

*Incandescent Lighting with an Intimate Mixture of Gas and Air, Impts. in.* L. Denayrouze, Neuilly, France. Eng. Pat. 1576, Jan. 22, 1896.

REFERENCE is made to Eug. Pats. 22,615 of 1894, 4491 of 1895, 7722 of 1895, and 11,053 of 1895, for methods of effectively mixing the gas and air before combustion in incandescent gas lighting. (1) When the coal-gas is taken at the service pressure and the air at atmospheric pressure, the mantle having the usual weight and volume, the combustible mixture should consist of 1 volume of gas and 3 to 5 volumes of air; the gases should be thoroughly mixed, and should have a velocity of 1.5 to 2.5 metres per second. (2) "Good mixture can be obtained by giving the gas and air an initial pressure higher than that in the service pipes and the atmosphere." Under these circumstances the aim should be to have a mixture containing 1 volume of gas with 3 or 4 of air, an intimate mixture, and a velocity of 6 to 12 metres per second. (3) When the incandescent bodies are not mantles of woven filaments, but are porous masses, relatively thick, such as may be obtained by using sponges, pumice stone, or retort carbon, impregnated with the usual solutions employed in making mantles from fabric, the quantity of combustible gas and the velocity of the mixture have both to be greater, the greater the mass of the body to be raised to incandescence, is, relatively to its volume.

The patentee claims "For incandescent gas lighting, the method of effecting an intimate mixture of air and gas under the combined conditions as to the composition, the pressure, and the velocity of the mixture herein-before stated."

—H. B.

*Incandescence Bodies for Illuminating Purposes, Impts. in the Manufacture of.* W. H. Wheatley, London. From F. Woerle, Stuttgart. Eng. Pat. 1681, Jan. 23, 1896.

MANTLES are to be made in the usual manner, using as impregnating fluid a solution of one of the following mixtures of salts:—(1) Thorium nitrate, 12 parts; erbium nitrate, 2.5 parts; zirconium nitrate, 9.0 parts; magnesium nitrate, 1.25 parts. (2) Zirconium nitrate, 12.25 parts; erbium nitrate, 9.0 parts; thorium nitrate, 2.5 parts; strontium nitrate, 1.25 parts.—H. B.

*Incandescence Bodies for Illuminating Purposes, Impts. in the Manufacture of.* W. H. Wheatley, London. From C. Schmid, Brussels. Eng. Pat. 1682, Jan. 23, 1896.

MANTLES are to be made in the usual manner, using as impregnating fluid a solution of one of the following mixtures of salts:—(1) Magnesia, 4 parts; zirconium nitrate, 85 parts; aluminium nitrate, 4 parts; erbium nitrate, 4 parts; strontium nitrate, 2 parts; didymium nitrate, 1 part. (2) Magnesia, 1.25 parts; zirconium nitrate, 12.5 parts; strontium nitrate, 1.25 parts; erbium nitrate, 10 parts; didymium nitrate, 0.25 part.—H. B.

*Incandescent Mantles, Impts. in.* P. Stiens, Clapham. Eng. Pat. 1841, Jan. 25, 1896.

MAGNESIUM chloride which has been heated to a high temperature in an open vessel and then cooled, is ground and mixed with 2 to 3 per cent. of powdered burnt chalk and sufficient gum tragacanth or gelatin to form a paste with water, and is then "moulded to the desired shape." Or, preferably, the mantle is made in the usual way by impregnating a fabric with a solution containing one part of the burnt magnesium chloride in two parts of nitric acid. In either case the "mantle" is dried, burnt, and then sprayed with a solution of burnt or unburnt magnesium chloride, and finally exposed to a high temperature. Thoria and other mantles are given "greater luminosity and strength" by the addition of burnt magnesium chloride. The patentee disclaims the use of magnesium chloride, but makes the one claim: "the employment, in the manufacture of incandescent mantles, of magnesium chloride which has first been exposed to a high temperature, substantially as described."—H. B.

*Liquid Fuel, Impts. in Apparatus for Burning.* A. Queutin, Brussels. Eng. Pat. 3560, Feb. 17, 1896.

THIS consists of a burner in which is comprised a chamber containing a suitable finely divided material (metallic chips or turnings, &c.), through which the hydrocarbon passes, the said chamber being heated through its length by the flame from a nozzle, at which is burnt the vapour so produced.

The arrangement and construction of a battery of these burners is also claimed.—A. S.

*Combustible Blocks [Briquettes] or Cakes from Particles or Dust of Waste Coal, Anthracite, and Lignite; A New Process for making.* E. Jumeau, Poudicherry. Eng. Pat. 23,076, Dec. 2, 1895.

AN agglutinative paste is made from pulverised tamarind seed by allowing it to slightly ferment, and then boiling. This paste is then mixed with particles of coal, anthracite, or lignite, in the proportion of about 10 per cent., and finally formed into blocks.—R. B. P.

*Treatment of Coke so as to render it suitable for Transport; A New or Improved Method or Process for the.* F. A. MacKinnon, South Kensington. Eng. Pat. 5916, March 17, 1896.

COKE, as it comes from the retorts, is treated with a spray of hot water or steam, holding in solution a binding cementitious material, preferably some cheap or waste matter containing glue or gelatin. The treated coke is next placed in moulds and subjected to pressure to form blocks of a convenient size for transport.—R. S.

*Gas Producers; Improved Process of and Apparatus for Facilitating the Burning of poor Coal and the like, chiefly applicable for Use in.* L. Bemelmans, Eng. Pat. 17,130, Aug. 1, 1896.

THE claim is for a process for burning fuel which settles, and consists in withdrawing, at very short intervals or continually, small quantities of ashes, and introducing air from the furnace above the settled ashes. There is also claimed the arrangements for carrying into practice the process in a rotary gas producer, a rotary annular gas producer, and in a gas producer having a cylindrical furnace and a fixed casing.—A. S.

*Gas Producers, Impts. in Safety Devices for.* A. C. Humphreys and A. G. Glasgow, Victoria Street, London; and New York. Eng. Pat. 23,904, Oct. 27, 1896.

CONSISTS in providing a water-gas apparatus (having airblast pipes with valves, separate take-off pipes for products of combustion and water-gas, and a valve for opening and closing the take-off pipe for products of combustion), with an arrangement for absolutely locking one or more valves against movement when another valve or valves is in a determined position.—R. S.

*Producing Gas or Vapour from Air and Liquid Hydrocarbons, Improved Process and Apparatus for.* A. I. van Vriesland, Amsterdam. Eng. Pat. 25,498, Nov. 13, 1896.

THE process consists in forcing air, at a suitable pressure and in a finely divided condition, through the liquid hydrocarbons or through fabrics saturated therewith, and leading off the mixture. Two forms of apparatus are shown, each consisting of a vessel having an internal chamber, into which the air is forced through a central tube ascending into it, and from which the air escapes through perforations, or through a fabric partition into the outer chamber, which contains the liquid hydrocarbon. The combustible gas escapes through an outlet at the top of the apparatus.

—R. S.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Uranium Carbide.* H. Moissan. Bull. Soc. Chim. 1897, 12—18.

WHEN uranium is heated in the electric furnace with excess of carbon, a definite crystalline carbide is formed

possessing the formula  $C_3U_2$ . When this substance is treated with cold water, it evolves about a third of its carbon in the form of a mixture of gaseous hydrocarbons rich in methane. The remainder is found in the form of a mixture of liquid and solid hydrocarbons and bituminous matters. Probably this decomposition is the result of polymerisations similar to those observed by Berthelot in his researches on the action of heat on hydrocarbons. The presence of the hydrogen in the gaseous mixture may, on the other hand, be due to a secondary action of a hydrated uranium oxide, which must be a powerful reducing agent. Péligot has shown that anhydrous uranium protoxide has a great avidity for oxygen, and that a suboxide exists which decomposes water.

The reaction of uranium carbide and water is interesting as affording a means of preparing a whole series of gaseous, liquid, and solid organic substances by the action of cold water on a metallic carbide.—T. E.

**Mineral Oils, Desulphurising.** W. Heinrici. Zeits. f. angew. Chem. 1897, 8.

HEUSLER (this Journal, 1896, 584) has stated that treatment with aluminium chloride removes all unsaturated hydrocarbons and sulphur compounds from mineral oils. The author investigates the applicability of this process to the lignite tar oils of Saxon Tauringia. A well-dried oil containing 1.2 per cent. of sulphur was treated with 5 per cent. of  $AlCl_3$  for 24 hours; after separating the resinous matter formed, and washing free from acid and distilling, an illuminating oil was obtained containing 0.27 per cent. of sulphur. By employing 10 per cent. of  $AlCl_3$  and continuing the treatment for 120 hours, the percentage of sulphur was reduced to 0.058, and by repeating the treatment it was possible to bring this down to 0.0085. According to Heusler, lubricating oils are obtained as a by-product; the author finds, however, that these heavy oils contain about 1.3 per cent. of sulphur and have a viscosity of only 4.5 at 20°, measured by Engler's viscosimeter. By distilling the residues which are formed, with steam, small quantities of an oil of disagreeable odour, and containing 4.4 per cent. of sulphur, were obtained; this oil was free from thiophene. It is to be noticed further that the oils may be desulphurised quite as efficiently and as cheaply by treating them with large quantities of strong sulphuric acid (66 B.). Thus, "Solar" oil treated with—

5 per cent. of Acid gave an oil containing 0.796 per cent. S.

10	"	"	"	0.620	"
15	"	"	"	0.241	"
25	"	"	"	0.135	"
50	"	"	"	0.100	"
100	"	"	"	0.063	"
200	"	"	"	0.046	"
400	"	"	"	0.0074	"

Acid of 40° or 50° B. had little desulphurising action, while fuming acid (10 per cent.  $SO_3$ ) gave no better results than acid of 66° B. The temperature at which the treatment took place was also found to be of little moment.

—T. E.

**Thiophene: Removal from Benzol by Means of Aluminium Chloride.** F. Heusler. Zeits. f. angew. Chem. 1896, 11, 750.

BENZOL (120 c.c.) which had been purified commercially by means of sulphuric acid and contained much thiophene, was heated to boiling in a reflux apparatus with aluminium chloride (5.8 grms.) and distilled, moisture being excluded. The distillate, after being washed with caustic soda and dried with calcium chloride, was found to be free from thiophene. This is in accordance with the results of Haller and Michel (this Journal, 1896, 706).

In his earlier experiments (*ibid.* 584), in which the benzol, after treatment with aluminium chloride, was steam-distilled, or the decanted product distilled, the author failed to remove all the thiophene. It seems probable that at the low temperature of the reaction, only a portion of the thiophene is converted into an insoluble resin, the rest forming an intermediate product which is soluble in benzol, and which regenerates thiophene in presence of water. In the

case of xylol, the intermediate product would be decomposed at the high temperature of the reaction, so that the decanted product may be treated with water without regeneration of thiophene.—N. H. J. M.

**Coal-Tar Bases.** F. B. Ahrens. Ber. 1896, 29, 2994—2999.

The author has isolated a new lutidine and collidine from coal tar, which he found to boil at 163.5—164.5 and 165—168° respectively.—D. B.

**Iron Carbide, A Pure.** E. D. Campbell. Amer. Chem. J. 1896, 18, 336.

See under N., page 145.

## IV.—COLOURING MATTERS AND DYES.

*Dyestuffs, An Attempt to classify Organic.*

S. de Kostanecki. J. Soc. Dyers and Colourists, 1897, 27.

The organic colouring matters are characterised according to their formulae by the presence of chromophors, which all contain double bonds. By arranging them according to the nature and the number of these chromophors, the author arrives at the following classification:—

### A. Dyestuffs containing a Single Chromophor.

C : C	Dibiphenylene-ethene.
C : O	Oxyketones, oxycoumarins, oxyflavones, oxyxanthones.
C : N	Auramine, thioflavine, quinoline yellow.
N $\begin{smallmatrix} \diagup O \\ \diagdown \end{smallmatrix}$	Nitro-colouring matters.
N : N	Azo colours.
N : N : O	Azoxy colours.

### B. Dyestuffs containing Several Chromophors.

#### (a.) Streptostatic Chromophors (Ketone Type).

C : C	Unsaturated oxyketones, indogenides, oxyindogenides, indigo.
C : O	Oxydiketones, oxydixanthones.
C : N	Hydrazone dyestuffs.
N : N	Disazo dyestuffs.

#### (b.) Cyclostatic Chromophors (Quinone Type).

C : C	C : O	C : N
C : O...	<div> <div> Aurins .....  Benzins .....  Phthaleins .....  Basic colouring matters  of the triphenyl-  methane group .....  Pyronines ..... </div> <div> } Oxyquinones.  } Indophenols.  } Nitrosophenols.  } Resazurine. </div> </div>	<div> Indamines.  Azines.  Safranines.  Indulines. </div>
C : N...		
C : N : O		

#### (c.) Streptostatic and Cyclostatic Chromophors.

This group comprises several complicated colouring matters, such as Alizarin Blue, Styrogallol, &c.—I. S.

**Colour Bases of the Triphenylmethane Series, Constitution of.** H. Weil. Ber. 29, 2677—2678.

In contradiction of the statement of v. Georgievic (Monatsh. Chem. 17, 10), the author observes that the red precipitate obtained by the addition of the calculated amount of soda-lye to a concentrated magenta solution is not a coloured base, but under all circumstances a mixture of rosaniline with its hydrochloride, the latter preponderating, the more concentrated the cold magenta solution employed, and the smaller the excess of soda-lye. The presence of magenta is easily proved by the fact that the precipitate, washed free from inorganic salts, begins to dissolve in water with the

characteristic colour, and contains chlorine (see this Journal 1896, 535). The author, moreover, points out that no conclusion can legitimately be drawn as to the constitution of the "red rosaniline base" from that of the "imid-oxide base," which is certainly different, and can be obtained from it by washing with hot water. As already stated (*loc. cit.*), owing to the little solubility of magenta in salt solutions, the alkali partly salts out some of the magenta, together with the rosaniline base. The following experiment supports the statement as regards the stability of magenta towards alkalis. If carbonic anhydride be passed into water warmed to 50°–60° C., in which rosaniline base is suspended, a solution is obtained containing rosaniline carbonate, which is neutral to litmus. On the addition of salt, rosaniline hydrochloride is precipitated and the colourless solution then contains sodium carbonate, and reacts strongly alkaline.—T. A. L.

*Parabenzoyltriphenylmethane and its Derivatives.*

P. Bourcet. Bull. Soc. Chim. 1897, 81–85.

*Parabenzoyltrinitrotriphenylmethane—*

is prepared by adding dry finely powdered parabenzoyltriphenylmethane to a large excess of fuming nitric acid at 0°. After three hours the liquid is warmed gently, and finally poured into excess of cold water. The nitro derivative thus obtained is purified by precipitating its solution in acetic acid with water, or may be crystallised by spontaneous evaporation of its solution in nitric acid. Fused with caustic potash, it yields benzoic acid, confirming the above formula. It softens at 70° and melts at 74–75°.

The corresponding *carbinol* is obtained by oxidation with chromic acid in acetic acid solution. The carbinol is colourless, but becomes bright red when exposed to light; it softens at 85° and melts at 88°.

By reducing the acetic acid solution of the carbinol with the theoretical quantity of zinc dust and precipitating with water, a green powder is obtained, the greater part of which is the *acetate of parabenzoylpararosaniline*—

This is not pure, because the hydroxyl group of the carbinol is reduced to some extent. The acetate of parabenzoyl pararosaniline dyes silk, wool, and cotton without a mordant; the colour produced is a pale green, which is not very fresh, but is fast to water, soap, and light.

When excess of zinc dust is employed in reducing the nitrated carbinol, the solution loses its red colour after a time, becoming pale yellow; it then contains the *leuco-base*  $C_6H_5CO.C_6H_3NH_2.CH(C_6H_4NH_2)_2$ , which may be crystallised from alcohol in greyish crystals. The last two compounds decompose without melting.—T. E.

*Methyl Iodide on Aqueous Solutions of Crystal Violet, Malachite Green, and Methylene Blue, Action of Hydrolysis of these Colouring Matters.* A. Rosenstiehl. Bull. Soc. Chim. (3), 15, 1299–1313.

THE alcoholised di- and triamine derivatives of triphenylcarbinol combine directly with methyl iodide in the cold, even in presence of much water, forming iodammonium derivatives, which can be titrated alkalimetrically after hydroxylation. The presence of acids retards the change, but does not prevent it, so that aqueous solutions of the magentas corresponding to the carbinols behave like the latter. The colouring matters above named, on solution in water, become partially hydrolysed into free acid and free base, which latter combines with the methyl iodide. This partial hydrolysis causes an increase in the electric conductivity of the solution.—G. H. B.

*Safranines, Constitution of.* R. Nietzki. Ber. 29, 2771–2773.

KEHRMANN'S discovery of phenylphenazonium (this Journal, 1896, 502) having at length definitely settled the question as to the safranine formula, the author again refers to his position in the matter, pointing out that a condensation

(*e.g.* in safranone) between the ammonium group and a hydroxyl group is in reality only an inner salt formation which frequently occurs between acid and basic groups, even between meta substituents, as, for instance, in *m*-diazobenzenesulphonic acid and in *m*-diazobenzoic acid. That aposafranine can be diazotised has been shown meanwhile by Kehrman. The strong basicity of the safranines, which the author has always considered a strong argument in favour of the azonium formula, is also borne out by Fischer's discovery that the hydrochloride of acetyl-aposafranine gives a carbonate with dilute sodium carbonate solution, for only relatively strong bases form stable carbonates. In the light of our present knowledge, only two views are tenable as regards the anhydrous safranine bases: either a condensation takes place (Nietzki), or there is a molecular change into the tautomeric *p*-quinone formula (Kehrman). The latter appears improbable, since the shade of the safranine colouring matters is but little altered by alkalis, although in the less basic members of the series—for instance, acetyl-safranine, which changes from yellow to violet—such a transformation may take place. In conclusion the author points out that Jaubert's analyses (usually nitrogen determinations) are not sufficiently in accord with theory to be accepted in support of this investigator's views and nomenclature proposals.—T. A. L.

*The Isorosindulines.* O. Fischer and E. Hepp. Ber. 29, 2752–2760.

THE name isorosinduline has been given (Annalen, 272, 306; this Journal, 1893, 669) to substances isomeric with the rosindulines, differing from these latter in containing the substituents ( $:NH$ ,  $:O$ ,  $:NC_6H_5$ ) in the benzene nucleus, whilst the rosindulines are substituted in the naphthalene ring—

Kehrman, however (Annalen, 290, 247; this Journal, 1896, 536), applies the name to another isomeride of rosinduline of the type—

for which the authors propose the name pseudorosinduline. In view of the relation between aposafranine and the simplest induline, it follows that the compound obtained by Nietzki and Otto (Ber. 21, 1600) from quinone dichloroimide and phenyl- $\beta$ -naphthylamine must be an isorosinduline. The present investigation was undertaken in order to determine in what respects this dyestuff is similar to aposafranine, and more especially as regards the indone, and also to study the action of bases such as aniline, *p*- and *o*-phenylene diamine, the action of alcoholic potash and of nitrous acid. When isorosinduline is treated with nitrous acid in presence of strong sulphuric acid, it is converted into a diazo compound, which, on decomposition with alcohol, yields, to all appearances, the same azonium compound as rosinduline when treated in a similar manner (Kehrman, Ber. 29, 1316). The azonium compound from isorosinduline is

converted by the action of ammonia into rosinduline, so that the conversion of the one isomeride into the other can in this way be effected. *Isorosinduline*, prepared according to Nietzki and Otto (*loc. cit.*), was purified by direct conversion into the well-crystallised nitrate by adding potassium nitrate to the alcoholic solution of the melt, diluted with water. Alcoholic solutions of the salts show a faint brownish fluorescence, and they are decomposed by alkaline carbonates. The isorosinduline base is very unstable to caustic alkalis and turns dirty bluish-violet. The dark bluish-violet sparingly soluble product gives blue salts with acids, and cannot be reconverted into isorosinduline. Much more stable to alkalis is *phenylisosinduline*—

obtained by condensing, in presence of hydrochloric acid, nitrosodiphenylamine (3 mol.) with phenyl- $\beta$ -naphthylamine (2 mol.) in an alcoholic solution. The nitrate crystallises well from 50 per cent. alcohol; the base dissolves with a blue colour in alcohol, benzene, or ether, and crystallises from benzene-petroleum ether. On heating with a mixture of acetic and hydrochloric acids to about 235° C. for 10 hours, *isorosindone* is obtained, but it can be produced much more easily by condensing nitrosophenol with phenyl- $\beta$ -naphthylamine. The substance is a very weak base, and after crystallisation from alcohol, melts at 224° C. The solutions of the salts are yellow. When heated with alcoholic potash, *isorosindone* is converted into *oxyisorosindone*—

as safranone is into oxyposafranone (Ber. 28, 2287). On heating with caustic potash and methyl iodide in methyl alcoholic solution, it is converted into methoxyisorosindone, which crystallises from alcohol in greenish needles, melting at 274° C. This substance dissolves in concentrated sulphuric acid with a bluish-violet colour, which turns brownish-red on dilution. By the action of aniline and aniline hydrochloride on isorosinduline in a concentrated alcoholic solution, *anilido-isorosinduline* (melting point 152° C.) is obtained, but the mode of conversion is not yet fully investigated.

The authors have further prepared *ms*-ethylisorosindoline from quinonedichlorodi-imide and ethyl- $\beta$ -naphthylamine, and also the corresponding rosindone from nitrosophenol and ethyl- $\beta$ -naphthylamine hydrochloride. The base, which melts at 178° C., dissolves in concentrated sulphuric acid with a reddish-violet colour, which, on dilution, passes through brownish-yellow to light yellow.

It would appear that the same phenylnaphthophenazonium chloride—

is obtained both from rosinduline and isorosinduline by means of the diazo reaction, and further investigation will show whether the isorosindulines alkylated in the azine ring, behave similarly.—T. A. L.

*Quinone-imide Dyestuffs, Configuration of.* W. Vaubel.  
J. für prakt. Chem. 1896, 292--304.

THE quinone-imide colouring matters may be arranged in two groups, one of which comprises such of them as do not contain azine rings—for example, the indanines and indophenols—and the other, the azines, that is, the eurhodines, oxazines, thiazines, safranines, and indulines.

The second group may be subdivided into the following classes :—

1. Compounds of which one form only is possible ; for example, phenazine.

2. Colouring matters which are capable of existing in two forms, namely, with a central ring like that of phenazine, and in a quinonoid form. The eurhodines and eurhodols belong to this class. Although the former of these have not yet been shown to exist in the quinonoid form, still it is probable that they do so, since the analogously constituted eurhodols so exist, yielding, as they do, with methyl iodide two monomethyl derivatives.

3. Colouring matters which exist in two quinonoid forms. This group comprises the Safranines, Magdala Red, Mauveine, and the Rosindulines.

4. Quinonoid colouring matters which have one form alone—the indulines.

Safranines and indulines differ in the colours of their bases and salts, thus :—

Saframines.		
Colour of base and salt .....		Red.
" concentrated HCl solution.....		Blue.
" " H <sub>2</sub> SO <sub>4</sub> " .....		Green.
Indulines.		
	Phenylindulines.	Indazines.
Colour of base .....	Brown-yellow.	Red.
" salt.....	Violet.	Blue.
" concentrated HCl solution.	Blue.	Green.

The fundamental difference in constitution between the two classes of colouring matters lies in the different valencies of the nitrogen atoms in the azine rings, as is seen in the formulae:—

5. Oxazine, oxazone, thiazine, and thiazone colouring matters, which may be regarded as derived from indulines and indones by the substitution of oxygen and sulphur for the inactive meso-phenylimido groups.—E. B.

*Quinone-imide Dyestuffs, Bromination of.* W. Vaubel.  
J. für prakt. Chem. 1896, 289—291.

*Phenosafranine* is powerfully acted upon by bromine, apparently with the production of a tetrabromo derivative, although the end of the reaction is difficult to perceive, owing to the intense red colour of the solution. It is probable that the bromine atoms take up the free positions ortho to the amido- and imido groups.

*Indazine* and bromine react slowly, the monobromo compound separating out from the solution.

*Rosinduline* also absorbs one atom of bromine, the completion of the reaction being in this case easily observed.

*Rosinduline disulphonic acid* reacts energetically with bromine. It was not determined how much of the latter was absorbed, or whether sulphuric acid was liberated.

*Rosindone* behaves similarly to the last compound. The product is precipitated in red flocks.

*Meldola's Blue* is likewise precipitated, but the termination of the reaction is seen with difficulty.

*Methylene Blue* reacts with two atoms of bromine, the monobromo derivative depositing as a tarry red mass and the course of the reaction being easily followed.

*Resorufin* and *resazurin* give tetrabromo derivatives. The bromination of the former proceeds according to the equations —

further action in the same way giving finally—

—E. B.

*Pyronine Dye-stuffs, Constitution of.* J. Biehringer.  
J. für prakt. Chem. 1896, 217—258.

The pyronines have the general formula—

in which R' represents an alkyl group, and R an alkyl, phenyl, or other group, or hydrogen.

They are obtained by condensing together aldehydes and *m*-hydroxydialkylanilines and oxidising the resulting compounds (Eng. Pat. 13,217 of 1889 and 18,606 of 1891; this Journal, 1890, 934, and 1892, 808). Only the compounds obtained from formaldehyde are at present manufactured. These appear in commerce under the names and shade marks Pyronine G (prepared from dimethyl-*m*-amidophenol), Pyronine B (from diethyl-*m*-amidophenol), and Pyronines O and GO, and are powders of a dark red colour with a green surface-lustre. Their aqueous solutions have a red colour and yellow fluorescence.

The constitution of the class is established by the formation of Pyronine G in the following way:—Dimethyl-*m*-phenylenediamine (2 mols.) when treated in alcoholic solution with hydrochloric acid ( $\frac{1}{2}$  mol.) and formaldehyde (1 mol.), gives tetramethyltetramidodiphenylmethane (m.p. 139°—141°), identical with the compound formed by nitrating tetramethyl-*p*-diamidodiphenylmethane, according to the method patented by Gerber and Co. (in sulphuric acid solution at 0; Ger. Pat. 60,505), and reducing the dinitro compound. It has, therefore, the constitution—

which is confirmed by its conversion, when heated with fuming hydrochloric acid, into an acridine derivative—

a compound (m.p. 181°—182°) dissolving in water with an orange-yellow colour, in aqueous acids with a red colour, and in concentrated sulphuric acid with a yellow colour and the blue-green fluorescence characteristic of acridine compounds. This is presumably the colouring matter known as Acridine orange (Ger. Pat. 59,179; this Journal, 1891, 537), the tetramethyltetramidodiphenylmethane requisite for the production of which is obtained by the condensation of *m*-amidodimethylaniline and formaldehyde.

The tetramethyltetramidodiphenylmethane obtained by either of the foregoing methods, gives by the diazo reaction the dihydroxy leuco base of Pyronine G.

Benzaldehyde condenses with dimethyl-*m*-amidophenol, yielding tetramethyldiamidodihydroxytriphenylmethane (Ger. Pat. 62,574), which, when oxidised, loses the elements of water and forms an Oxy-malachite-green Pyronine, a pink colouring matter formerly prepared from dimethyl-*m*-amidophenol and benzotrichloride (Ber. 22, 3004), and named Rosamine. The dihydroxy leuco compound of this, after being benzoylated, gives on oxidation, a green dyestuff, which is easily saponified and condensed into the Pyronine.

When oxidised in alkaline solution, the Pyronines yield xanthone derivatives; thus, Pyronine G gives tetramethyldiamidoxanthone—

a compound crystallising from alcohol in yellow prisms, which lose alcohol of crystallisation at 130° and melt at 240°—242°. It dissolves readily in alcohol, acetone, chloroform, carbon bisulphide, and xylene, less readily in benzene, and with difficulty in ether and petroleum spirit. Its acetone, chloroform, alcohol, and concentrated sulphuric acid solutions display a blue fluorescence, its aqueous acid solutions a fine green fluorescence and yellow colour; the concentrated acid solutions stain the skin yellow. On reduction and subsequent oxidation in acid solution, the xanthenes are reconverted into the corresponding Pyronines.

—E. B.

*Thiobenzophenone.* L. Gattermann and H. Schulze.  
Ber. 29, 2944—2945.

In a previous paper (Ber. 28, 2869), the authors have described the preparation of thiobenzophenone by heating benzophenone with phosphorus pentasulphide in benzene. The product obtained, however, always contained more or less benzophenone, and purification, owing to the instability of the thio-compound, was not possible. According to the present paper, the pure product can be obtained by the action of alcoholic potassium sulphide on benzophenone chloride. This latter is prepared by heating 12 grms. of benzophenone and 20 grms. of phosphorus pentachloride under an inverted condenser in an oil-bath to about 230° C., and subsequently fractionating in a vacuum, when the ketone chloride distils at 193° C. under a pressure of 30 mm. For the preparation of the thiobenzophenone, 1 gm. is mixed with 4.5 c.c. of alcoholic potassium sulphide solution (1 c.c. contains 0.1124 potassium sulphide). The mixture heats spontaneously, turns blue, and potassium chloride is precipitated. After cooling, water is added, the thio-ketone is extracted with ether and distilled under a pressure of 14 mm., when it passes over at 174° C. as a dark blue oil, solidifying to blue needles. It melts at a lower temperature than benzophenone, and can only be preserved in an atmosphere of carbonic acid in the dark. On warming with alcoholic potash it is quickly converted into benzophenone. The same change takes place gradually when exposed to the air. With hydroxylamine it yields benzophenone oxime, and on heating with finely divided copper, it gives quantitatively tetraphenylethylene.

—T. A. L.

*Naphthacetyl (p-Acetamido-α-Naphthol).* O. N. Witt and J. Dedichen. Ber. 29, 2945—2954.

The azo dyestuffs from α- and β-naphthol possess very different properties, for whilst β-naphthol yields compounds in which the azo group enters ortho to the hydroxyl, α-naphthol can give two series of azo dyestuffs, according to whether the azo group enters para or ortho to the hydroxyl. The former most frequently takes place, and the resulting dyestuffs usually possess such strongly marked phenolic and basic properties, giving salts not only with metallic oxides but also with acids, that, technically, they are of little value, owing to the fact that the formation and decomposition of these salts is accompanied by a change in shade. The case is, however, otherwise with those derivatives of α-naphthol in which the azo group enters ortho to the hydroxyl. The dyestuffs having this constitution possess a brightness and stability superior even to that of the β-naphthol derivatives, and, moreover, they are bluer in shade, which renders them still more valuable. These ortho derivatives are, however, as a general rule, only formed directly when the para position is occupied—such as is the case, for instance, with α-naphthol-*p*-sulphonic acid. With the object of obtaining non-sulphonated ortho derivatives, the authors have prepared the acetyl compound of *p*-amido-α-naphthol and describe some of its reactions. The compound is obtained by mixing 100 grms. of dry *p*-amidonaphthol hydrochloride with 50 grms. of fused sodium acetate, and adding a mixture of 50 grms. of acetic

anhydride and 100 grms. of glacial acetic acid. The melt becomes warm and solidifies to a crystalline mass of naphthacetyl (1,4-hydroxyacetylnaphthalide). After distilling off a part of the acetic acid, the product is washed with water and re-crystallised from alcohol, when it forms thin white needles, melting at  $187^{\circ}\text{C}$ ., soluble in the ordinary solvents. It is easily soluble in caustic alkalis and also dissolves in sodium carbonate solution and in ammonia. The shades obtained by combining it with diazo compounds are similar to those of  $\beta$ -naphthol, and by impregnating cotton cloth with its solution in sodium carbonate, various shades can be obtained by the use of different diazo compounds.

Diazo Compound from	Naphthacetyl.	$\beta$ -Naphthol.
Aniline.	Scarlet.	Orange-red.
$\psi$ -Cumidine.	Bluish-red.	Yellowish-scarlet.
$\alpha$ -Naphthylamine.	Reddish-violet.	Bordeaux.
$\beta$ -Naphthylamine.	Bordeaux.	Bluish-red.
Benzidine.	Violet.	Reddish-violet.
Tolidine.	Bluish-violet.	Violet.
Dianisidine.	Indigo blue.	Violet.

The dyestuff obtained from aniline has been examined, and crystallises from pyridine in matted needles, melting at  $268^{\circ}\text{C}$ . It was not found possible to hydrolyse the compound, and the methyl ether (m.p.  $220^{\circ}\text{C}$ .) was also stable. Naphthacetyl also combines with diazo-sulphonic acids, yielding dyestuffs giving shades on wool and silk from an acid bath similar to but bluer than those from  $\beta$ -naphthol. All the azo compounds from naphthacetyl can be reduced by means of stannous chloride (Ber. **21**, 3468; this Journal, 1889, 276), but the resulting amidonaphthacetyl could not be purified, and it was therefore oxidised with ferric chloride to the corresponding quinone, which melted at  $220^{\circ}\text{C}$ . This compound, which on reduction with sulphurous acid gives the hydroquinone (m.p.  $187^{\circ}\text{C}$ .), reacts with *o*-phenylene diamine, yielding acetylphenonaphthacetylurhodine, and this, on hydrolysis with concentrated hydrochloric acid, forms dark red needles of phenonaphthacetylurhodine hydrochloride. The base crystallises from xylene and melts at  $294^{\circ}\text{C}$ . As a further proof that the azo group enters ortho to the hydroxyl, it is stated that the acetyl quinone obtained above is easily converted by alcoholic potash into oximidonaphthol and hydroxynaphthoquinone, and, moreover, it gives, like phenanthraquinone, a compound with bisulphites. The acetylurhodine can also be obtained by the joint oxidation of naphthacetyl and *o*-phenylene diamine with potassium ferricyanide. The nitroso derivative of naphthacetyl crystallises from glacial acetic acid in golden needles, melting at  $203^{\circ}\text{C}$ ., and gives an emerald-green precipitate with ferrous and a blackish-violet precipitate with cobalt salts. If in the above preparation of naphthacetyl, the acetic anhydride be replaced by an equivalent weight of other anhydrides, corresponding derivatives are obtained. Thus, for instance, butyrylamidonaphthol is formed by treating a mixture of 30 grms. of amidonaphthol hydrochloride and 15 grms. of sodium acetate with 23 grms. of butyric anhydride and 100 grms. of glacial acetic acid. The compound crystallises from alcohol in colourless needles, melting at  $161^{\circ}\text{C}$ . Similarly obtained, valerylamidonaphthol melts at  $205^{\circ}\text{C}$ ., and benzoylamidonaphthol melts at  $229^{\circ}\text{C}$ . This latter compound can also be obtained by the Baumann-Schotten method by cautiously adding an alkali to the aqueous solution of equimolecular proportions of amidonaphthol hydrochloride and benzoylchloride. All these derivatives in their behaviour to alkalis and diazo compounds act similarly to naphthacetyl.—T. A. L.

**Anthraquinone, Hydroxylamine Derivatives of.** R. E. Schmidt and L. Gattermann. Ber. 1896, **29**, 2931—2943.

1,5-dihydroxylamine anthraquinone—

is obtained by the reduction of 1,5-dinitro-anthraquinone with stannous chloride in an alkaline solution. On acidification a brownish red precipitate is obtained, which is extracted with cold acetone and recrystallised from hot pyridine. The pure product forms dark brownish-red needles showing a green metallic lustre. It is sparingly soluble in acetone, alcohol, and wood spirit, but dissolves easily in hot pyridine. The dibenzoate crystallises in long garnet-red needles melting at  $188^{\circ}$ , and the tribenzoate forms orange-yellow crystals melting at  $228^{\circ}$ . For its conversion into amidohydroxyanthraquinones, 10 grms. of the hydroxylamine derivative are dissolved in 850 grms. of concentrated sulphuric acid and 150 grms. of water. The mixture is heated rapidly to  $100-110^{\circ}$ , the reaction being completed as soon as the solution assumes a yellow colour. The chief products of the reaction are two isomeric diamido compounds, called  $\alpha$  and  $\beta$  by the authors, a third substance,  $\gamma$ , being produced in small quantity. Their separation is effected by the difference in their behaviour towards solvents. The  $\beta$ -compound dissolves easily in hot dilute sulphuric acid (15 per cent.  $\text{H}_2\text{SO}_4$ ), and separates out again on cooling.  $\alpha$  and  $\gamma$  are more insoluble in sulphuric acid than  $\beta$ . The latter is readily soluble in alkalis, whilst  $\alpha$  and  $\gamma$  are almost insoluble;  $\gamma$  is easily soluble,  $\alpha$  sparingly soluble, in acetone. The following are the distinctive properties of the three compounds:— $\alpha$  dissolves in hot nitrobenzene with a violet-blue colour, and forms long lustrous needles resembling brass in appearance;  $\beta$  is readily soluble in acetone, forming a red solution, and crystallises in green lustrous crystals. Both compounds have the composition  $\text{C}_{14}\text{H}_9\text{O}_2(\text{OH})_2(\text{NH}_2)_2$ . They dissolve in sulphuric acid with a yellow colour, and on adding boric acid to the solution,  $\alpha$  assumes a pure blue, and  $\beta$  a violet colour, exhibiting characteristic absorption spectra, consisting in the case of  $\alpha$  of a sharp line situated in the red and a fainter line in the green, whilst the lines given by  $\beta$  are situated in the blue rays;  $\gamma$  gives a yellow colour with sulphuric acid, which boric acid does not alter. However, on heating it to  $80-100^{\circ}$  in sulphuric monohydrate with a 10 per cent. solution of boric acid, a bluish-red solution is obtained, showing a cinnamon-red fluorescence and exhibiting an absorption spectrum in the green rays, the blue being entirely extinguished.

The authors have prepared the same compounds by the action of 1,5-dinitro-anthraquinone on sulphur sesquioxide (sulphur dissolved in fuming sulphuric acid). Having obtained the compound  $\alpha$  by synthesis from anthrarufin, they conclude that it is di-*p*-amidoanthrarufin, its constitution being represented by the formula—

Analyses of the compound  $\gamma$  gave numbers pointing to the formula for diamidohydroxyanthraquinone. However, owing to the difficulty experienced in the purification, the authors refrain from speaking with absolute certainty on this point. They have also prepared the following derivatives of anthraquinone:—1,5-nitrohydroxylamine anthraquinone, 1,8-dihydroxylamine anthraquinone, 1,8-nitrohydroxylamine anthraquinone, and 1-monohydroxylamine anthraquinone.—D. B.

## PATENTS.

*Azo Dyes, Impts. in the Manufacture of.* S. Pitt, Sutton. From L. Cassella and Co., Frankfort-on-the-Maine, Germany. Eng. Pat. 2446, Feb. 3, 1896.

The azo dyestuffs formed from salicylic acid have the power of forming sparingly soluble lakes with chrome mordants, by virtue of their possessing a hydroxyl and a carboxyl group ortho to one another. The lake-forming property is, however, not so well defined as in the alizarin dyestuffs, and with a view to increasing it, the patentees have introduced two salicylic acid groups into an azo dyestuff by combining with *m*-diamines, diazo compounds derived from substances having the general formula—

where  $X.NH_2$  represents an amine like  $\alpha$ -naphthylamine. The combination takes place in such a way that the *m*-diamine is combined either with two molecular proportions of the above substances, or else first with diazosalicylic acid and subsequently with the diazo-azo compound. The most valuable products are obtained from nitro-amidosalicylic acid, since the introduction of the nitro group increases the fastness to light and also produces a yellower shade. Moreover, no change in shade is to be observed on chroming, which is the case when salicylic acid itself is used. By varying  $X$  in the above general formula the shades may be varied in the direction either of the red or violet end of the spectrum,  $\alpha$ -naphthylamine, however, giving the darkest shades. Easily soluble dyestuffs are obtained by employing 1.3' or 1.2'-naphthylamine sulphonic acid in place of  $\alpha$ -naphthylamine. The following is a typical example:—The diazo compound from 39.6 kilos. of (1.3.4.5) nitro-amidosalicylic acid and 14 kilos. of sodium nitrite is combined with 28.6 kilos. of  $\alpha$ -naphthylamine in a solution faintly acid with hydrochloric acid. When the combination is complete, the dyestuff, after filtering, is dissolved in soda-lye, 14 kilos. of sodium nitrite added, and the mixture is acidulated at about 0° C. The sparingly soluble diazo compound thus formed is filtered off and added to a solution containing 10.8 kilos. of *m*-phenylene diamine kept alkaline with sodium carbonate. The dyestuff separates as a dark brown precipitate.—T. A. L.

*Disazo and Trisazo [Cotton Browns and Blacks] Colours or Dyes, Impts in the Manufacture of.* T. R. Shillito, London. From J. R. Geigy and Co., Basle, Switzerland. Eng. Pat. 2771, Feb. 6, 1896.

The specification relates to the production of dyestuffs from the alkyl derivatives of 2.1'.3'-amidonaphthol sulphonic acid by combination with tetrazo compounds. The usual *p*-diamines are employed, such as benzidine, diamidodiphenyltolyl, tolidine, ethoxybenzidine, diamidodiphenol ether, *p*-phenylene diamine, 1.4.2'-naphthylene diamine sulphonic acid, &c. Either symmetrical or mixed disazo dyestuffs can be obtained, and in the case of the latter, certain of them can be further diazotised and combined. The shades obtained from the disazo compounds vary from brown to violet, greyish-blue, grey, and black, and dye unmordanted cotton. The following example gives the quantities employed in the formation of a trisazo dyestuff:—75.6 kilos. of the mixed disazo compound obtained from equimolecular proportions of tetrazodiphenyl, 2.1'.3'-methyramidonaphthol sulphonic acid, and 2.1'.3'-amidonaphthol sulphonic acid, is suspended in 1,000 litres of water together with 35 kilos. of hydrochloric acid (21 B.) and diazotised with 7 kilos. of sodium nitrite. The diazotisation is complete after several hours, and the resulting compound is poured into 300 litres of water containing 11 kilos. of resorcinol and 30 kilos. of sodium carbonate. The dyestuff forms a black precipitate, which is filter-pressed and dried. It gives silver-grey to black shade on unmordanted cotton.—T. A. L.

*New Sulpho Acid 1.4.2-Naphthylene Diamine Sulphonic Acid] and of [Blue] Colours derived therefrom, Production of.* Levinstein, Lima, and L. Levinstein, Manchester. Eng. Pat. 2946, Feb. 10, 1896.

THE 1.4.3'- or 2.4'-naphthylene diamine sulphonic acid of Eng. Pat. 15,444 of 1893 (this Journal, 1894, 801), is

decomposed by nitrous acid. The acid of the present specification, however, gives a diazo compound which reacts with amines, phenols, and their derivatives, and the resulting products are capable of being again diazotised, and give, on combination with various components, disazo dyestuffs yielding yellow to deep black shades. This last operation can also be performed on the fibre. In addition to its employment for the production of azo dyestuffs, the new 1.4.2-naphthylene diamine sulphonic acid can also be used in the manufacture of safranines, indulines, and allied compounds. The acid is obtained by combining aniline or other suitable aromatic amine with 1.2-naphthylamine sulphonic acid and reducing the resultant product with iron and hydrochloric acid. After making alkaline, and blowing off the aniline with steam, the new acid crystallises out on acidifying the filtrate. It oxidises easily in a neutral or alkaline solution, forming a yellow crystalline substance, which has a greenish-yellow fluorescence in an aqueous solution. The new acid is converted into a diazo compound by dissolving 23.8 kilos. of it in 200 litres of water containing 5.3 kilos. of sodium carbonate, precipitating with 100 kilos. of 20 per cent. acetic acid, and diazotising with 7.2 kilos. of sodium nitrite. The compound so obtained, is gradually added to an alkaline solution of 35 kilos. of  $\beta$ -naphthol disulphonic acid R. The dyestuff, after salting out, is filter-pressed and dried. It gives blue shades on wool from an acid bath. This dyestuff can then be further diazotised by dissolving 62 kilos. of it in 300 litres of water, acidulating with 70 kilos. of hydrochloric acid (20° B.), and diazotising with 7.2 kilos. of sodium nitrite. The solution, which originally was violet-blue, changes to a deep red, and the new diazo compound, which can, if required, be salted out, is combined with an alkaline solution of  $\beta$ -naphthol. The disazo colour produced, forms after salting out, a dark blue precipitate, which dyes wool deep blue to black from a neutral or acid bath.—T. A. L.

*Colouring Matter [Bluish-Green] from Substituted Fluoresceins, Manufacture of.* O. Inrny, London. From "The Farbwerke vormals Meister, Lucius, and Brüning," Höchst a.M., Germany. Eng. Pat. 3,000, Feb. 10, 1896.

According to Baeyer (Annalen, 183), when tetrabromofluorescein is strongly heated with concentrated sulphuric acid, it is converted into bromocerulein, but the yield is poor. Dyestuffs of the nature of cerulein and in good yield, may, however, be obtained by the employment of monohydrated or fuming sulphuric acid. Thus, 20 kilos. of tetrabromofluorescein are added to 100 kilos. of fuming sulphuric acid containing 20 per cent. of  $SO_3$ , and the mixture is kept at 125° C. until a sample neutralised with alkali and mixed with brine no longer gives a coloured filtrate. The excess of fuming sulphuric acid is then decomposed by adding 40 kilos. of sulphuric acid of 66° B. and 100 kilos. of 60° B., after which the dyestuff is precipitated by pouring the melt into ice and water. An almost black paste is thus obtained which can be used directly for dyeing. It is insoluble in water, very sparingly soluble in alcohol, but dissolves in sulphuric acid with a cherry-red, and in alkalis and alkaline carbonates with a bluish-green colour. The alkali salts can be salted out from these solutions. The product dyes chrome-mordanted wool bluish-green, very fast to air and fading. The dyestuff undergoes a further change and gives much greener shades by heating the dry substance with 10 times its weight of ordinary sulphuric acid to 130° C. for 3–4 hours and subsequent precipitation with water, when it is filtered off and washed. The two processes can, of course, be combined, if it be desired, to at once obtain the greener shade. Other substituted fluoresceins suitable for this invention are: disubstituted bromofluorescein, di-iodo- $\alpha$ -tetra-iodo-fluorescein, tetrabromo- and tetra-iodo-dichlorofluoresceins, tetrabromo- and tetra-iodo-tetrachlorofluoresceins.—T. A. L.

*Polyazo Dyestuffs [Blacks], Impts. in the Production of.* S. Pitt, Sutton. From L. Cassella and Co., Frankfort-on-the-Maine, Germany. Eng. Pat. 3028, Feb. 10, 1896.

THIS is an extension of Eng. Pats. 16,699 of 1889; 5141 of 1893; 9529 and 25,918 of 1894 (this Journal, 1890, 935;

1894, 246; 1895, 478 and 1041). The dyestuffs there mentioned are obtained by using *m*-phenylene diamine, *m*-tolylene diamine, and resorcinol as end-components. It has now been discovered that these substances can be replaced by their azo derivatives, and if these be suitably chosen, new dyestuffs having valuable properties may be obtained. The general formula of the new compounds is—

where P is the radicle of a *p*-diamine, and N:N.R.OH the diazo compound of an amidophenol or amidonaphthol sulphonie or carboxylic acid. The following is a typical example. The tetrazo derivative from 21.4 kilos. of dianisidine is combined with 21 kilos. of  $\gamma$ -amidonaphthol sulphonie acid in an alkaline solution, and the intermediate compound thus obtained is run into a solution in sodium carbonate of the product obtained by the diazotisation of 15.3 kilos. of amidosalicylic acid, and combination with 11 kilos. of *m*-phenylene diamine in an acetic acid solution. A black precipitate gradually forms. The product dyes unmordanted cotton a deep black, and can be fixed with chrome mordants. As *p*-diamines, the most useful are benzidine, tolidine, diamidodiphenol ether, diamidodiphenylmethane, and *p*-phenylene diamine, whilst R can be either  $\gamma$ -amidonaphthol sulphonie acid, 2.1'.3.3'-amidonaphtholdisulphonie acid, amidosalicylic acid, or *p*-amidophenol sulphonie acid.—T. A. L.

**New Phthalic Colouring Matters [Yellows, Reds], Manufacture of.** O. Imray, London. From "The Farbwerke vormals Meister, Lucius, and Brünning," Höchst a. M., Germany. Eng. Pat. 3966, Feb. 21, 1896.

CERTAIN phthalic acids, when treated with ammonia or primary bases of the fatty or aromatic series, are converted into new and valuable dyestuffs. The resultant products still possess an acid character and give alkaline salts, and are obtained from the nitrofluoresceins and their derivatives. For example, 10 kilos. of dinitrofluorescein and 10 kilos. of water are stirred to a paste with 7.5 kilos. of 22–24 per cent. ammonia. The mass heats spontaneously to about 40°–45° C., and after a short time thickens, and shining lamine separate out. Brine is added, and the mass is filtered, the residue consisting of the ammonium salt of the new product, which can be purified by dissolving in water and precipitating with salt. The product dyes wool a pure yellow, unaffected by alkalis. The colour dyes evenly and is fast to light. If, in the above example, the water and ammonia be replaced by 15 kilos. of aniline and the melt be heated to 120° C., condensation with separation of water takes place, and the resultant dyestuff, after removing the excess of aniline with hydrochloric acid, dyes wool a reddish-yellow. A brick-red dyestuff for wool is obtained, as in the first example, by employing the same quantity of dichlorodinitrofluorescein in place of the dinitrofluorescein.

—T. A. L.

**Greenish-Blue Colouring Matters or Dyes of the Malachite Green Series, Impls. in the Manufacture of.** T. R. Shillito, London. From J. R. Geigy and Co., Basle, Switzerland. Eng. Pat. 5068, March 6, 1896.

IN Ger. Pat. 80,982, the patentees described a process for the production of the orthosulphonie acid of Malachite Green, and observed that the position of the sulphonie acid group ortho to the methane carbon conferred upon the product, properties of dyestuffs belonging to the Patent Blue series. In the present specification a method is described for the direct production of similarly constituted colouring matters from *o*-benzaldehyde sulphonie acid. This product can be obtained by heating together *o*-chlorobenzaldehyde with an aqueous solution of neutral sodium sulphite in an autoclave to 190°–200° C. for about 8 hours. The formation of the new dyestuff is carried out as follows:—186 kilos. of a 10 per cent. solution of *o*-benzaldehyde sulphonie acid is boiled with 30 kilos. of dimethylaniline and 3 kilos. of sulphuric acid for about 15 hours. Sodium carbonate is then added, and the excess of dimethylaniline is distilled off. After dilution to 5,000 litres, the solution

is made acid with hydrochloric or acetic acid, and the resulting leucosulphonie acid is oxidised with lead peroxide. The lead is precipitated by means of sodium sulphate, and the filtered solution is made alkaline with ammonia and evaporated to dryness. If the dimethylaniline in the above example be replaced by 60 kilos. of ethylbenzylaniline sulphonie acid and the leucosulphonie acid obtained, be oxidised with 100 kilos. of a 30 per cent. lead peroxide paste, the resulting colouring matter forms a bronzy powder, soluble in water with a blue colour, and dyeing wool a pure greenish-blue from an acid bath.—T. A. L.

**New Colouring Matters Dyeing from Blue-Green to Blue, and of New Chloro Derivatives and Sulphonie Derivatives of Benzoic Aldehyde therefor; Manufacture of.** O. Imray, London. From "The Society of Chemical Industry in Basle," Basle, Switzerland. Eng. Pat. 25,128, Nov. 9, 1896.

A process has been formerly described for obtaining bluish-green colouring matters, which dye from an acid bath, by condensing benzyl-*o*-toluidine or benzyl-*o*-toluidine sulphonie acid with benzaldehyde and oxidising the resultant leuco compound. According to the present specification, the benzaldehyde is to be replaced by a whole series of chloro and sulphonie derivatives of benzaldehyde, yielding in a similar manner derivatives of triphenylmethane, which on oxidation give bluish-green to blue dyestuffs. The new sulphonie acids of benzaldehyde are obtained either by sulphonating *o*-chlorobenzaldehyde, when chlorobenzaldehyde sulphonie acid (CHO:Cl:SO<sub>3</sub>H = 1:3:6) is formed, or else by the action of sodium bisulphite on this latter product or on dichlorobenzaldehyde under pressure in an autoclave. The products so obtained are condensed with two molecules, the same or different, of secondary or tertiary aromatic amines, such as methyl-*o*-toluidine, dimethyl- or diethylaniline, methylbenzylaniline sulphonie acid, &c., forming leuco compounds, which on oxidation with peroxides or chromic acid yield greenish-blue to blue dyestuffs. The following may serve as an example of the method employed:—120 kilos. of an 8 per cent. solution of *o*-benzaldehyde sulphonie acid and 28 kilos. of benzyl-*o*-toluidine sulphonie acid are heated on the water-bath for about eight hours. The melt is dissolved in 200 litres of water and the leuco trisulphonie acid is precipitated with salt. After drying, 20 kilos. of the dry product are dissolved in 500 litres of water and oxidised after adding 40 kilos. of 10 per cent. sulphuric acid with the requisite quantity of lead peroxide. When the reaction, which takes about one hour, is complete, the mixture is neutralised with chalk, filtered, and evaporated. The dyestuff forms a dark green powder easily soluble in water to a blue solution, and gives blue shades on wool from an acid bath. (See also this Journal, 1893, 672.)

—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

**Pentosans, Proportion of, in Cotton-Wool.** H. Suringar. Chem. Zeit. Rep. 1896, 290.

See under XXIII., page 167.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

**Defects in Dyeing, and their Remedies.** J. J. Hummel. J. Soc. Dyers and Colourists, 1897, 2–12.

**Defects due to Fibre.**—The white specks occasionally noticed in plain-dyed calicoes have been shown by Crum to be due to unripe fibres ("Dead cotton"), which have no affinity for certain colouring matters. The remedy of this defect lies mainly in the hands of the spinners. The ginning, scutching, carding, &c., should be as perfect as possible, not only to remove "dead cotton," but also to get rid of bits of cotton seed, the oil of which is apt to cause similar defects (see also this Journal, 1885, 720). In some cases, however, the dyer may hide the defect by selecting such dyestuffs as possess the property of covering even unripe cotton fibres.

in wool, too, there are occasionally abnormal fibres known as "kemps," which have little or no affinity for colouring matters, and cause imperfections in dyed woollen cloth similar to those due to "dead cotton" in dyed calicoes. Here the remedy rests partly with the sheep farmer and partly with the wool sorter. Here, again, the dyer may occasionally cover the defect by choosing such colouring matters as tend to dye the kemps, by chlorinating the wool, or by slightly modifying the dyeing process (see J. Soc. Dyers and Colourists, 1896, 141).

But, apart from such structural defects, even different qualities of the same fibre often possess a different attraction for colouring matters, and an irregularity in the dye of woollen cloth is often due to an injudicious blending of different qualities of wool. Irregular weaving, the introduction of yarns not uniform in diameter, of different tensions, or twisted in opposite directions, are equally liable to cause irregularity in the appearance of the dye.

Again, many colouring matters, e.g. induline, dye the individual fibres so irregularly that the cloth or yarn exhibits a speckled appearance. This defect may be overcome by oxidising the fibre previous to dyeing, either by means of potassium bichromate or a solution of bleaching powder.

Brown discolorations or dark spots have been traced to the well-known presence of sulphur in wool, which produces dark-coloured sulphides of copper, tin, or lead, with which metals the material had accidentally come in contact. These spots are formed the more readily when the wool is in an alkaline condition. In special cases it may be desirable to remove the active sulphur from the wool by repeated successive treatment of the wool with calcium hydrate, hydrochloric acid, and water, as proposed by Chevreul.

*Defects caused by Operations preliminary to Dyeing.*—Special care must be exercised by the bleacher to prevent rust stains, by the immediate removal of the cotton from the kier after the soda-boil, by a careful search for iron nails in the roof or elsewhere, by periodical whitewashing of kiers, and painting of iron pillars, brackets, &c., and the use of wooden pegs instead of nails in wooden benches, &c. Holes, cuts, and tears in the cloth must be prevented by avoiding tremulous boiling in the kiers, or the casual entrance of cinders into the washing machines, and by the renewal of cracked pot-eyes or wooden rails, when the latter have worn to a cutting edge by the friction of the travelling cloth.

Cloth is often tendered by an insufficiency of liquor in the kiers, by undissolved particles of chloride of lime, and allowing piles of cloth soaked with acid standing too long or exposed to air currents, which concentrate the acid in certain portions. The author mentions an interesting case investigated by Witz, who traced the brown spots, frequently accompanied by minute holes, which often appear in bleached calicoes after steaming, to the presence of undissolved particles of bleaching powder on the cloth. Witz also found that with strong solutions of bleaching powder, oxycellulose is formed, which greatly increases the affinity of the cotton fibre for certain basic colouring matters, notably so for Methyl Violet; and his investigations led him also to the discovery of the oxidising action which bleaching powder exerts on animal fibres, thereby increasing their affinity for dyestuffs.

In connection with wool, the all-important preliminary operation is that of scouring. Caustic soda, and all so-called substitutes, should be avoided, and only well-recognised scouring agents, such as sodium carbonate, soap, ammonia, &c., should be used. Excessive concentration or high temperatures in the solution, and an unduly prolonged application, are to be avoided. Equally important is the necessity of completely removing the scouring agent from the wool by thorough washing, as in many cases the presence of alkali in the scoured wool may lead to defects in mordanting or dyeing.

Skin-wool, which has been removed from the pelt by lime, and invariably highly charged with calcium carbonate, can only give poor, dull, indifferent colours, unless the lime is previously removed by rinsing such wool with dilute hydrochloric acid, followed by washing and scouring.

Wool, which has been submitted to the action of sulphuric acid in the process of "carbonising," has acquired, by reason of this treatment, a much greater attraction for colouring matters than ordinary wool; so that an imperfect bleaching of "extracted" with ordinary wool may lead to irregularity of colour. The same may happen if the acid has not been completely removed from the "extracted" wool by washing, or, better still, by the use of sodium carbonate solution.

*Defects due to Water.*—The necessity for soft water, or its correction by well-known methods where calcareous waters only are available, is insisted on.

*Defects due to Mordanting.*—Full and well-nourished colours can only be obtained with mordant colours, when the mordant used has been in proper condition and rightly applied. With wool, if the mordanting bath is too acid, comparatively little mordant is fixed on the fibre; and if "too neutral," the mordant is insufficiently, irregularly, or superficially fixed, giving poor, speckled-looking colours which rub off. The right proportion of mordant to the amount of dyestuff, the quantity of material and water employed, should be experimentally determined and then rigidly adhered to.

Over-chroming is another frequent cause of poor and badly fixed colours, which defect can never occur if the chromium is fixed as a chromic oxide salt. The author deprecates the long-continued use of the same chrome-bath with the customary freshening up.

Similar defects as with chrome may also occur with aluminium, tin, and iron mordants, if an insufficiency of tartar or similar assistant be employed.

Other defects connected with bichrome mordanting are the irregularities caused by the reducing action of light on exposed portions of the mordanted material, and by allowing the mordanted goods to lie in a heap before washing for an undue length of time, which causes "feeding" in the lower portions of the mass, subsequently dyeing to a darker colour.

Alum for mordanting purposes should be free from iron; and if iron vessels only are available, a block of zinc should be introduced into the bath to prevent any iron from being dissolved. In calico-printing, the saddening influence of iron, perchance present in the alumina employed, is counteracted by the addition of stannous chloride, which, by its reducing action, maintains the iron in the soluble ferrous state. The substitution of the neutral aluminium sulphocyanide for the acetate has removed the possibility of iron being dissolved from the steel "doctors" during printing.

*Defects due to the Dyestuffs employed.*—As an instance of mutually incompatible dyestuffs the author mentions a case where a mixture of nitro-alizarin and an alizarin bisulphite colour was used. The mixture had often been used with success, but now and then the colours came up entirely off shade. An inquiry into the circumstances elicited the fact that if the colours were mixed beforehand, and allowed to stand for some time before being added to the dye-bath, the nitro-alizarin was affected by the reducing action of the sulphurous acid of the bisulphite colour—a decomposition which did not take place if added in the dilute state direct to the dye-bath.

Similar defects, which are either inherent in the dyestuffs employed, or are due to the methods of application, are then discussed in connection with aniline black, indigo, &c., and methods are suggested which may prevent the rubbing off of vat-dyed woollen cloth.

*Defects due to Machinery* usually comprise streaks, spots, stains, cuts, tears, &c. Spots are frequently caused by water drops from the roof or from the interior of a hood, e.g. over drying cylinders, which should be avoided by suitable precautions. Lifting may be due, among other causes, to the arrangement of the dye-vessel, the position of the steam-pipe, &c. Other marks in the pieces may be due to friction, or too vigorous working with a wooden rod.

*Defects due to the Methods employed.*—These are of the most varied character, and must, as a rule, be ascribed to ignorance or want of experience on the part of the dyer. Full shades on wool with many dyes are apt to bleed and rub off if not boiled long enough during the dyeing process. This is the case, for example, with the Congo and the Alizarin

colours. On the other hand, long boiling must be avoided when dyeing delicate shades with logwood, otherwise the colours are rendered dull and off shade, owing to the oxidation and destruction of the colouring matter. By slightly acidifying the bath with acetic acid, this defect may be avoided.

Entering the goods into a dye-liquor which is too hot, tends to a superficial fixing of the colouring matter, which is usually accompanied by rubbing off or irregularity of colour. On the other hand, entering at too low a temperature may, with certain dyestuffs, e.g. Acid Violets, cause the production of spots, due to a separation of the colour acid in a tarry form. By entering at about 70–100° C., the colour acid remains in perfect solution, and at the same time dyes level shades.

No fixed rule as to the most suitable temperature at which to enter the goods can be given, as this varies with the character of the dyestuffs employed. But it is advisable always to enter at the highest temperature which is consistent with the production of bright and level shades.

Bronzy patches with aniline colours, or irregularity of shade, may be caused by freshening up the bath with dyestuff without lifting the goods from the liquor, or by omitting the filtration of the colour solutions.

*Defects caused in the Finishing Operations.*—A very common one is that of pieces being "listed," i.e., appearing of a paler or darker colour at the selvages, which is due to "feeding," by the pieces having been left to drain in a heated and unwashed condition, or to the operation of blowing steam through the pieces while wrapped tightly on perforated rollers. The steam, in tending to force its way between the folds of cloth towards the selvages, causes there an accumulation of any loose impurities that may have been present in the cloth, and are carried along with the steam.

A common source of annoyance experienced with many colours during the scouring or milling of dyed pieces is that of "bleeding," or the staining of neighbouring fibres in the cloth. To prevent this, only such colouring matters should be used as are not liable to this defect. Certain of the Congo dyestuffs, viz., those containing the salicylic acid group, have the property of forming lakes; and with these the defect of "bleeding" is cured by passing the dyed cotton through various metallic solutions, whereby the colouring matter is fixed as an insoluble salt. Alizarin colours and some of the basic colours fixed with tannic acid, &c., may be prevented from bleeding on to neighbouring parts by adding to the soap-bath some finely divided tannate of antimony precipitate, which immediately attracts any loose basic colour in the soap-bath, and renders it insoluble. (See also this Journal, 1896, 590.)—I. S.

*Crimp Patterns on Mousseline de Laine, A Method of Producing.* E. Knecht. J. Soc. Dyers and Colourists, 1895, 21–22.

By subjecting wool to the treatment of certain chemical agents, its felting properties may be either increased (e.g., by means of mercury nitrate) or decreased (e.g., by means of chromic acid or free chlorine).

Based on this well-known fact, the author has worked out the following process for producing permanent crimps on light woollen cloth. The scoured mousseline de laine is printed in stripes of  $\frac{1}{2}$  in. or more with sulphuric acid of 10°–20° Tw., suitably thickened with British gum. It is then dried and passed for about two minutes through a solution of bleaching powder at about 2° Tw. The material is well washed to remove acid, &c., and is then milled with soap until the crimp is sufficiently prominent. The crimped cloth may subsequently be dyed any colour, but with some colouring matters there will be a distinct difference of shade between the plain and raised portions. If the printed stripes are too narrow, the crimping does not succeed well. Equally unsatisfactory were the experiments made with thick material.—I. S.

*Soupled Silk, The Dyeing of, by the Aid of Formaldehyde.* H. Silbermann. Färber Zeit. 7, [30], 479–480.

HITHERTO it has been impossible to dye a full black with logwood from a soap-bath on soupled silk, because, as is

well known, silk which has been soupled is made worthless by even very dilute soap solutions at temperatures above 65° C. The author has now found that the process patented by Ris-Kummer (Eng. Pat. 15,152, 1895; this Journal, 1895, 965), of rendering the gum insoluble by means of formaldehyde in hot water, is also applicable to soupled silk, which absorbs the formaldehyde very energetically. He has treated the silk for two hours in a bath with 3 per cent. of a 40 per cent. solution of aldehyde (commercial "formaline"), rinsed, and dyed it with logwood in a soap-bath. The results are stated to have been most satisfactory: the fibre has lost very little, whilst the lustre and "feel" have been improved.

The treatment with aldehyde must take place subsequently to the weighting, as the absorbent power of the silk is considerably lowered by this process.—I. S.

*Milling with Acids.* Leipziger Monatschr. für Text. Ind. through Färber Zeit. 7, [29], 466–468, and [30], 486–487.

THE article is based on occasional notes, and embodies the experience of the author whilst working the process. The following are the chief points of interest:—

Cloth dyed in such a manner that it may be subjected to the acid treatment without detriment to its colour, is not much inferior in general appearance and weight to goods milled with soap. But goods that had been dyed in the wool (i.e. before spinning) are liable to have their shade slightly altered. This, however, can be guarded against in the preliminary process. The author is of opinion that acid-milled cloth feels more spongy and less firm than cloth milled with soap; the latter is also better felted. Pieces milled with acids are certainly not better than those milled with soap.

Gray pieces that have to be "carbonised" and are to be dyed in the piece are milled directly after carbonising, requiring only the requisite quantity of water. Cloth that has been dyed in the wool, and which does not require carbonising, is first carefully scoured, and, after removal of all surplus moisture by the hydro-extractor, is milled with sulphuric acid of 2–3° B. In milling by the acid process it is essential that the goods should previously be well scoured, as they cannot be subsequently treated with soap without deterioration. Care must be taken, therefore, not to soil the pieces during or after the milling process.

With the acid process it is more difficult to mill lengthwise than with the soap process. Hence, when desiring to mill lengthwise, the soap process is preferable. It is also of importance that the goods should not be allowed to remain long after milling before the acid is removed, since the continued action of the acid may affect the shade of colour; moreover, continued contact of the goods with metals, whilst saturated with acid, may cause stains.

The author says that, on the whole, the acid process of milling has so far given satisfactory results. There is a considerable saving in soap, whilst in the case of pieces that have to be carbonised, no additional acid even is required, that already in the cloth, being sufficient.

The relative merits of the two processes are then discussed, and, with the exception of cost, which is in favour of the acid process, the author is inclined to think that the soap process has many advantages over the former. The colours, in the case of dyed goods, are more brilliant by the latter process, and there is less risk of stained or soiled goods, which, in the case of the acid process, may be a serious matter, since the goods cannot be subsequently scoured in soap liquors without deteriorating their quality.

The most suitable acid is sulphuric acid. There should not be an excess of moisture, as better and more uniform results are obtained when the cloth is not too wet. Of late, acid of only  $1\frac{1}{2}$ ° B. has been used, with better results, the shades being less liable to injury, if the goods were allowed to lie in the wet state than with the stronger acid used formerly.—I. S.

*Paranitraniline Red in Dyeing and Printing.* A. G. Green. J. Soc. Dyers and Colourists, 1897, 17–21. (See also this Journal, 1896, 590, 649, and 901.)

UNTIL quite recently it was believed that a very low temperature was a necessary condition for the diazotisation of

*p*-nitraniline, and that the diazo compound was very unstable. This is now known to be erroneous, for by proper conditions the diazotisation can be readily performed without the employment of ice, or taking any particular care as to temperature. Moreover, instead of being easily decomposed, the diazo solution is very stable, and will keep almost unchanged for two or three weeks. It is only when mixed with sodium acetate that it becomes unstable.

The following points must be observed for successful diazotisation:—(a) The mixture of *p*-nitraniline and hydrochloric acid must be fairly concentrated. (b) The nitrite should be added without intermission, but slowly. (c) Vigorous stirring during the operation. (d) A sufficient excess of acid. (e) Copper vessels must not be used. (f) The hydrochloric acid should be as pure as possible.

10 lb. of *p*-nitraniline and 2 gals. of cold water are briskly stirred in an enamelled or wooden vessel to form a perfectly even paste. 2½ gals. of hydrochloric acid of 28° Tw. are then added, stirring for another 15 minutes, after which 6 gals. more of cold water are added. To this mixture is added, *all at once*, with constant stirring, a solution of 5½ lb. of sodium nitrite in 1½ gals. of water. If, after 15 or 20 minutes' stirring, the solution does not give a blue colour when tested with "iodine paper," a little more nitrite solution is added, until the latter is present in slight excess.

Directions for printing are given.—I. S.

*Lactic Acid as an Assistant in Mordanting Wool.* C. Archer. *Färber Zeit.* 7, [30], 477—479. (See also this Journal, 1896, 196 and 540.)

As an acid, lactic acid is weaker than either tartaric or oxalic acids, and ranks about equal with the very feeble chromic acid. This is argued from the fact that whilst lactic acid can liberate chromic acid from neutral chromates, chromic acid can also liberate lactic acid from neutral lactates. All the chromic acid, however, is not liberated by the lactic acid (unless the latter be in large excess), and the mixture consists of an acid chromate and a lactate. These salts do not decompose each other, even on boiling. But if both acids be present in the free state, they react very energetically, the solution turning green in a very short time even at ordinary temperatures.

The action of tartar, tartaric acid, and more especially of oxalic acid on chromic acid, is very slow and feeble. By boiling, the action of tartaric acid is increased, the solution turning green. But a mixture of the solutions of oxalic and chromic acid retains its yellow colour, even after prolonged boiling.

It follows from this that lactic acid is a much better reducing agent for chromic acid than either oxalic or tartaric acid, but in order to use it to best advantage, both acids should be present in the free state. This may be effected by adding to the mordanting bath the requisite quantity of sulphuric acid to liberate the chromic acid from the salt employed.

Under such conditions the whole of the chromic acid present may be quantitatively reduced to chromic oxide. Thus, if a solution of 30 parts of lactic acid (50 per cent.), 15 parts of potassium bichromate, and 5 parts of concentrated sulphuric acid in 1,000 parts of water, be boiled for two hours, there results a green precipitate of chromic oxide, and a clear, colourless liquid, free from any trace of chromic acid, the originally strongly acid solution having become almost neutral.

If an excess of sulphuric acid be taken, then chromium sulphate or chrome alum would be formed instead of chromic oxide. On the other hand, it is necessary that the lactic acid should be present in excess; and it has been found that for the complete reduction of the chromic acid, the quantity of lactic acid (50 per cent.) to be used, should be twice the weight of that of the bichromate. If less be taken, the reaction does not proceed as above stated. If, for instance, a solution of 25 parts of lactic acid (50 per cent.) and 30 parts of potassium bichromate be boiled, a brown, unalterable precipitate of basic chromium chromate

is speedily formed, leaving potassium bichromate in solution.

In the presence of wool the reactions proceed as above described; but inasmuch as the wool (being of a basic character) absorbs some of the acid, it is necessary to increase slightly the quantity of sulphuric acid.

Based on these results, the following proportions and mode of working are recommended. The well-scoured and rinsed wool is worked for 20 minutes in a bath at 75° C., to which are gradually added 1.5 per cent. of concentrated sulphuric acid, 1.5 per cent. of potassium bichromate dissolved in water, and 3 per cent. of lactic acid (50 per cent.). The temperature is then raised to boiling, and so maintained for half an hour, when the wool will be found to be of a pure green colour, and the bath perfectly colourless. The above quantities are said to be sufficient for the fullest shades.

For thick felts, army cloths, &c., which are difficult to penetrate, the following modification of the process is recommended. The goods are first boiled for half an hour with the bichromate and sulphuric acid only, when the steam is shut off, the lactic acid added, and the goods run for half an hour longer. The temperature is then again raised to boiling, and the goods worked for another 20 minutes.—I. S.

*Albumins. Putrefaction of.* O. Emmerling. *Ber.* 29, 2721—2726.

WHEAT-FLOUR gluten was separated from starch and fatty matters, and mixed with water, calcium carbonate, and a little calcium phosphate and magnesium sulphate. After sterilising, a pure culture of *proteus vulgaris* was added, and the whole maintained at a temperature of 37°. After four days a considerable quantity of gas was evolved, containing 46 per cent. of CO<sub>2</sub>, 38 per cent. of hydrogen, and 16 per cent. of nitrogen. After the sixth day a smell of putrefaction was noticed, and in 14 days the whole mass was in solution. The following substances were recognised in the liquid: phenol, ammonia, trimethylamine, betaine, formic, acetic, butyric, and small quantities of higher fatty acids. No ptomaines could be detected.

Egg albumin was examined in a similar way, except that *staphylococcus pyogenes aureus* was used in place of *proteus* and the experiment was conducted in an atmosphere of hydrogen. Little gas was evolved, and in 14 days the albumin was converted into a thin liquid. Phenol, indole, scatol, trimethylamine, ammonia, formic, acetic, propionic, butyric, oxalic, and succinic acids, with small quantities of higher fatty acids, were the only products isolated.

Experiments destined to decide whether *staphylococcus* contains an enzyme capable of splitting up polysaccharides, showed that this is not the case for cane sugar, glycogen, maltose, and milk sugar.—T. E.

## PATENTS.

*Textile Fabrics, An Improved Method of and Apparatus for Printing upon.* A. S. Young and W. Rumney and Co., Ltd., Ramsbottom. Eng. Pat. 5153, March 7, 1896.

With the object of printing metallic or other dry powders on textile fabrics, an adhesive medium suitable for carrying the powder is first printed by means of an engraved copper roller, and this is followed by a second roller on which a facsimile of the design engraved on the first roller has been cut in relief. This second roller is furnished with the dry powder from an ordinary colour box, and is adjusted so that the design falls exactly on the top of the previous impression. By using two or more relief rollers, the fabric may be printed with several differently coloured powders.

—R. B. B.

*Textile Fabrics and Materials, Impts. in Kiers for Bleaching and similarly Treating.* E. Deakin, Bolton. Eng. Pat. 6028, March 18, 1896.

In the bottom of the kier is inserted an inverted hopper-shaped casting, which, together with a perforated grating, forms the false bottom of the kier. Near the bottom of this casting are small openings communicating with the space below the false bottom, and inside the casting is a coil of

steam pipes. Above the casting, and connected with it, is a vertical circular pipe, and inside this and concentric with it, is a smaller tube consisting of a series of short tapering pipes fitting loosely over one another in such a way as to allow of a passage of liquid from the inner pipe to the space between the two pipes. When steam is first admitted and circulation set up, the liquor ascends in the outer vertical pipe and descends through the inner tube into the casting described; when, however, the whole of the liquid reaches the boiling point, it flows over the top of the spurt pipe and is deflected on to the fabric in the kier.—R. B. B.

*Dry Materials [more particularly Fibrous Substances], Improved Process for Treating, with Liquid.* A. Vogel-sang, Dresden, Germany. Eng. Pat. 26,195, Nov. 23, 1896.

A vacuum is produced in a hermetically closed vessel, in which the dry fibrous materials are placed, and liquid is rapidly conveyed into the vacuum chamber by means of a high-pressure pump, and immediately brought to a pressure of at least 50 atmospheres. The process is stated to be applicable to the dyeing and bleaching of dry, raw, unboiled fibrous material, such as loose cotton, cops, twilled hanks, or meshed fabrics.—R. B. B.

## VII.—ACIDS, ALKALIS, AND SALTS.

*Sulphuric Acid: Cleaning Transport Tank-Waggons.*

R. Nörrenberg. Chem. Ind. 1896, 19, 553.

The wrought-iron cylindrical vessels, used as tanks (Rhenania Fabrik), are flushed with a good stream of water introduced through the manhole, and this flushing water, with the suspended mud, is drawn off through a tube inserted in the manhole and reaching to the lowest point in the tank, to a partially exhausted reservoir. Drainage taps, which are liable to leakage, are thus dispensed with.

The reservoir should be fitted with a vacuum gauge and a tube to show the level of the contained liquid.

The cleaning of each tank can be done without risk, by two workmen in from half an hour to one hour.—J. T. C.

*Permanganic Acid, Reduction of, by Manganese Peroxide.* H. N. Morse. Ber. 30, 48—50.

The evolution of oxygen, noticed by Meyer and Recklinghausen, in acidified solutions of potassium permanganate which have been employed to absorb hydrogen or carbonic oxide, is due, according to the present author, to the manganese peroxide formed in the oxidation, and now present in the solution. The same evolution is produced by all reducing agents, and also by the addition of a small quantity of precipitated manganese dioxide to acid permanganate solutions. The rapidity of the evolution in this latter case is dependent upon the temperature, the amount of oxide present, and the degree of acidity of the solution.

Investigation of the reaction led to the following conclusions:—

1. Permanganic acid and potassium permanganate are reduced by precipitated manganese dioxide, with liberation of three-fifths of the active oxygen of the permanganic acid.

2. The observed instability of standard potassium permanganate solution is attributable to this cause. Such solutions should be carefully filtered through asbestos, and then stoppered up.

3. Permanganate solutions free from suspended oxide show a high degree of stability in the dark or in diffused daylight; in direct sunlight however, decomposition occurs.

4. The oxide resulting on complete reduction of a neutral potassium permanganate solution contains the whole of the potassium originally present in the salt, and the supernatant solution is therefore neutral.

5. Whether the precipitated peroxide is formed by the gradual decomposition of a neutral permanganate solution or by the addition of manganese sulphate to an acidified solution of permanganic acid, the ratio of oxygen to manganese only remains normal (i.e., 2:1) so long as unreduced permanganate or permanganic acid is present. In the absence of permanganic acid or its salts, the oxide loses oxygen even at ordinary temperatures.

6. In the presence of permanganate or permanganic acid, this lost oxygen is again taken up.

The lower oxides of manganese produced in these reactions appear to form members of a homologous series, and may be represented by the following formulae:— $MnO$ ,  $5MnO_2$ ,  $MnO$ ,  $10MnO_2$ ,  $MnO$ ,  $15MnO_2$ ,  $MnO$ ,  $20MnO_2$ , &c.

The author has also studied the reaction of lead peroxide on permanganic acid, in presence of nitric acid, and represents it by the equation—

This reaction is complicated by the presence of the manganese peroxide, and is not so simple as that described above, which is represented as follows:—

The reaction with lead peroxide forms a good method for the preparation of oxygen, and possesses the advantage that the gas current can be regulated by suitable heating of the mixture, or by altering the rate at which the permanganate solution is added to the mixture of lead peroxide and nitric acid.—J. T. C.

*Corrosion of Cast and Wrought Iron by Fused Caustic Soda under Pressure.* Scheurer-Kestner. Bull. Soc. Chim. 15, [24], 1250—1252.

The author relates the circumstances attending the explosion of an iron boiler in which caustic soda was being heated to 250° C., at a pressure of 4 atmospheres. Laboratory experiments showed that pressure increases the rapidity of corrosion of cast or wrought iron by fused caustic soda.—G. H. B.

*Alkali Sulphates, Action of Hydrochloric Acid Gas on.* A. Colson. Comptes rend. 1896, 123, 1285.

EXPERIMENTS were made in which relatively large quantities of sodium sulphate were subjected to the action of dry HCl in tubes having their open ends dipping into mercury, so that the tension attained after prolonged contact could be determined for different temperatures. Under these conditions, the mercury rose slowly in the tubes, until it attained a stable height, showing, at 10° C., a tension of 2 mm.; at 100°, of 15 mm.; at 120°, of 23.5 mm.; and at 175°, of 77 mm. Doubling the proportion of the gas (the salt being still in large excess), gave practically the same results. Hence it is concluded that the tension of the HCl gas is independent of its mass, this being characteristic of heterogeneous dissociation. It was also found that a somewhat rapid rise of temperature in the experiments increased the pressure far beyond the stable tension for the temperature attained. In one case a rise to 175° in the tube gave a tension exceeding 200 mm., which after a time fell to 78 mm., showing a change of phase in the reactions. From these and other experiments described, the conclusions are drawn, first, that sodium sulphate is attacked cold by dry HCl; and, second, that there are several series of tensions of the gas, corresponding to reactions expressed by—

Of these, the second equation, answering to the greatest liberation of heat, represents the more stable effects. Finally, the author concludes that the action of hydrochloric acid gas on sodium sulphate involves a succession, or rather, a superposition of phenomena of heterogeneous dissociation.—E. S.

*Iron Salts from Pyrites, Manufacture of [for Sewage Purification].* A. and P. Buisine. Rev. Chim. Indust. 1896, 297.

THE salts of iron, particularly the ferric salts, have of late years increased in importance as precipitants proposed for sewage purification, the ferric salts yielding the best results (see this Journal, 1893, 354 and 1052). For the manufacture of ferric sulphate by this process 100 parts of sulphuric acid at 60° B., in the hot state in which it comes

from the Glover tower, are run into a cast-iron boiler which can be heated by direct heat. To this hot acid, from 40 to 50 parts, according to the desired acidity of the finished product, of very finely ground burnt pyrites are added, and the mixture well agitated. A reaction sets in, which is finished by the application of heat, and results in conversion of 95 per cent. of the burnt pyrites into the ferric salt. The finished product is a dry greyish powder of anhydrous ferric sulphate, slowly soluble in cold, readily soluble in hot water. Ferric chloride in the solid state is obtained by passing hydrochloric acid gas containing very little moisture—i.e., in the state in which it leaves the salt-cake furnace—over burnt pyrites, placed in moderately thick layers in suitable chambers. The action starts in one point and proceeds rapidly through the whole mass until practically the whole of the ferric oxide has been converted. For the preparation of ferrous salts, incompletely burnt pyrites, containing still at least 10 per cent. of sulphur, are treated with sulphuric acid at 60° B. in the manner above described for the production of ferric sulphate. The residual sulphur in the pyrites is eliminated during this treatment in the form of sulphuretted hydrogen, which reduces the ferric sulphate formed at the same time into ferrous sulphate, free sulphur separating out at the same time. The crude product thus obtained is dissolved in boiling water for crystallisation. The insoluble residue consists almost entirely of sulphur.

—C. O. W.

*Sulphuretted Hydrogen, Absorption of, by Liquid Sulphur.*  
H. Pelabon. *Comptes rend.* 1897, **124**, 35–37.

THE author summarises his results as follows:—

1. Hydrogen begins to combine with sulphur at about 250° C.
2. Between 250° and 350°, combination is not complete.
3. Liquid sulphur, maintained at a temperature above 170° C., in presence of sulphuretted hydrogen, absorbs a considerable quantity of this gas.
4. The quantity of gas absorbed is greater the higher the temperature, pressure remaining constant.
5. In all cases the gas is liberated at the moment of solidification of the sulphur; "the disengagement of the gas is a consequence of the solidification."
6. Pure hydrogen is not absorbed (in the sense of solution) by liquid sulphur.

It is interesting to compare this result with the observation that liquid selenium, heated in the presence of a mixture of hydrogen and seleniuretted hydrogen, absorbs a considerable proportion of this latter gas.—J. T. C.

## PATENTS.

*Cyanogen Compounds, Impts. in Methods of Separating, from Gas Liquor or other Solutions containing Cyanogen Compounds.* H. Bower. Philadelphia, U.S.A. Eng. Pat. 361, Jan. 6, 1897.

See under II., page 129.

*Chloride Solutions for Disinfecting and like Purposes, An Impt. in the Preparation of Electrolysed.* E. Hermite, E. J. Paterson, and C. F. Cooper, London. Eng. Pat. 2197, Jan. 30, 1896.

THE electrolysed chloride solution prepared according to specifications 15,384 of 1887 (this Journal, 1888, 764), 8177 of 1889 (1890, 733), 18,370 of 1893 (1894, 170), 22,279 of 1893 (1894, 271), and 6,497 of 1894 (1895, 492), loses strength and deteriorates with time, and it is claimed that this may be prevented by the addition to the chloride solution, either before or after electrolysis, of small proportions of alkali, preferably on account of cheapness, caustic soda or milk of lime.—G. H. R.

*Ferrocyanides from Sulphocyanides, Impts. in the Manufacture of.* J. T. Conroy, F. Hurter, and J. Brock, Liverpool. Eng. Pat. 3869, Feb. 20, 1896.

A MIXTURE of calcium sulphocyanide and of ferrous chloride solutions is heated in an autoclave under pressure, with iron, preferably reduced iron, in excess of the proportion indicated by the equation—

When the reaction is completed, the precipitate, consisting of ferrous cyanide and ferrous sulphide, may be digested with caustic soda solution if it be desired to obtain sodium ferrocyanide; but if the potassium salt be wanted, the precipitate is first treated with strong hydrochloric acid to dissolve out the iron sulphide, the hydrogen sulphide evolved being collected. The ferrous cyanide is then washed, and digested with potassium hydroxide solution to obtain potassium ferrocyanide. If the first-named process be used, the ferrous sulphide left after the digestion with soda, is treated with hydrochloric acid to obtain ferrous chloride for application in decomposing calcium sulphocyanide, the hydrogen sulphide given off being collected as before.—E. S.

*Zinc Oxide, Impts. in the Manufacture of [from Zinc Sulphate].* Dr. W. Hanpe and Dr. C. Schnabel, Clausthal, Germany. Eng. Pat. 3906, Feb. 20, 1896.

ANHYDROUS zinc sulphate and carbon, both finely divided, are mixed in the proportions indicated by the equation—

and heated for about two hours at a regulated temperature approximating to 650° C. The sulphurous acid evolved, may be utilised in obtaining sulphuric acid for acting on zinc ores to produce the zinc sulphate required in the process.—E. S.

*Nitrites of Soda and Potash, Impts. in the Manufacture of.* L. G. Paul, London. Eng. Pat. 4743, March 3, 1896.

TO 100 parts of sodium nitrate, melted in an iron pan, 40 parts of caustic soda and 14 parts of sulphur are added in successive portions, with agitation, the temperature being kept too low for the sulphur to inflame. After mixture, the temperature is raised until the melt froths, when the agitation is renewed. The increased temperature is maintained until the melt clears, when it is run off. The same process is used in the reduction of potassium nitrate, equivalent weights of the nitrate and hydroxide being taken, answering to the proportions used in the former case. The nitrite obtained is separated from the sulphate simultaneously formed by fractional crystallisation.—E. S.

*White Arsenic, Impts. in the Manufacture of.* T. P. Sims and W. Terrill, Swansea. Eng. Pat. 9076, April 30, 1896.

CERTAIN by-products, consisting chiefly of iron arsenide, and known as "slurrie" and "hardhead," are melted and run into a vessel which is fixed; instead of the usual movable vessel known as the "Bessemer converter." This vessel has a tap hole, nozzles for introduction of an air-blast, and it is surrounded by a water-jacket. The charge is melted in an adjacent furnace and then allowed to run into the fixed vessel or converter. The blast of air is introduced just before the molten charge is run in, and is maintained

throughout the operation. When arsenious anhydride (which is collected) ceases to be evolved, the molten contents are run out. The slag, consisting chiefly of ferric oxide, is separated from the metal or speiss, containing iron, copper, silver, &c.—E. S.

*Evaporators, Improvements in and relating to the Discharging of Salts and the like from.* J. Foster, Pollokshields, Glasgow. Eng. Pat. 928, Jan. 14, 1896.

See under I., page 129.

*Nitric Acid Regenerator.* Dr. J. Walker, Basel, Switzerland, and C. Lehmann, Muskau, Prussia. Eng. Pat. 20,290, Sept. 14, 1896.

THE apparatus for regaining nitric acid from its products of reduction is a cylindrical chamber constructed in two sections, the upper section resting on the lower, near the bottom of which is an inlet for the gases. A series of superposed porous earthenware plates, having holes, each vertically over that beneath it, is arranged within the chamber, the gas outlet being immediately below the highest plate. Each hole is occupied by a tube, resting on its flange, and covered by a cap in the form of an inverted cup, provided with a series of notches at the rim, on which it rests, allowing passage for water in one direction and for the gases in the opposite direction. Water enters the chamber through a spray head in the cover. Several modified forms of cups to the depending tubes are described and shown.—E. S.

## VIII.—GLASS, POTTERY, ENAMELS.

*Crude Kaolin, Saarau (Silesia).* H. Seger and E. Cramer. Thonind. Zeit. 20, [56], 819.

SAARAU kaolin is derived from a deposit of kaolinised granite. Its fusing point approximates to 35° of the Seger cone, and its proximate composition is:—quartz, 38.05; felspar, 0.61; clay substance, 61.34 per cent.; the ultimate constituents being silica, 67.09; alumina, 23.77; and iron (reckoned as oxide), 0.70; with 8.50 per cent. of loss during calcination. The clay—assuming the iron to be present as a mechanical admixture, probably from pyrites—is composed of alumina, 39.8; silica, 46.3; water, 13.9 per cent. Analyses of the kaolin from the upper workings of the same deposit, made by G. Richters in 1868, showed 75.88 per cent. of total silica, and 17.31 per cent. of alumina, so that the present material is much richer in clay substance.

Most of the quartz is removed by sedimentation washing, the purified kaolin then consisting of silica (combined), 40.89; quartz, 7.38; alumina, 36.3; iron oxide, 1.16; loss during calcination, 12.57 per cent., which—expressed in percentage terms of burnt kaolin—is equivalent to silica, 55.0; alumina, 41.4 per cent.—C. S.

*Temperature Determinations.* [Pottery Furnaces.] Hecht Centralbl. f. Glas-Ind. 1896, 11, 311 and 321.

WHEN employing the Le Chatelier pyrometer the chief points to remember are, first, that the resistance of the wire leading to the galvanometer should not greatly exceed 1 ohm. The instrument may be ordered with sufficient length of wire to reach from the furnace to the manager's office (whereby the progress of the heating can be readily observed), and the resistance of this will be taken into consideration in standardising the apparatus. Secondly, the platinum and platinum-rhodium wire must be of such a length that its temperature at the point of connection with the copper wire leading to the galvanometer is not appreciably higher than that of the room. The wires of the elements, which are insulated from each other by porcelain capillaries, must be protected from the heating gases, and particularly from carbon, by a porcelain tube glazed on the outside. The galvanometer must be firmly fixed on to a table, wall bracket, or other support, so that the perpendicular coincides with the intersection of the fixed lines on the lower ring, and the checking screw must be loosened gradually, otherwise the suspensory threads of the frame may be broken or strained and give rise to inaccuracies.

The crank handle on the case is for the adjustment of the pointer against the zero point of the scale after the instrument is in position and before the current is passed.

The instrument enables the manager to control, from a distance, the work of the furnace men, and to see that they are performing their task properly.

In considering the feasibility of replacing the Seger cones by the Le Chatelier pyrometer for pottery work, it should be remembered that time as well as temperature forms an important factor in the production of the pyrochemical effect to be attained in the kiln, and that the Seger cones undergo, in the processes of sintering and fusing, similar changes to those sustained by the ware, and therefore constitute a valuable means of control. The two methods in conjunction, however, afford more complete information respecting the firing temperature of various kinds of ware than has hitherto been obtained.

The author submits a table of the fusing points of the Seger cones from No. 022 to No. 36, calculated from data obtained by testing No. 022 and others up to No. 10, which reduces the figures at which the higher numbers were formerly estimated. It is stated that the Le Chatelier instrument is employed in conjunction with the d'Arsonval galvanometer and the Seger cones at the Royal Porcelain Works at Berlin, Dr. Schott's glass laboratory in Jena, Messrs. Villeroy and Boch's works, and at the Mahlstadt Cement Works, with satisfactory results.—C. S.

*Glass, Calculation of the Yield of a Charge of.* R. Hohlbaum. Sprechsaal, 29, [46], 1273—1274.

THE shrinkage of the charge is due to the volatilisation of acids, water, and other impurities, alkalis, and (where fluorspar is added as a flux) silicon fluoride, the two first-named being, however, all that have usually to be considered in practice. The actual percentages of loss sustained by the chief substances used in glass-making are: of the sodium sulphate employed, 62 per cent. as  $\text{SO}_2$ ; sodium carbonate, 53 per cent. as  $\text{CO}_2$ ; potassium carbonate, 45 per cent. as  $\text{CO}_2$ ; calcium carbonate, 46 per cent. as  $\text{CO}_2$ ; barium carbonate, 25 per cent. as  $\text{CO}_2$ ; strontium carbonate, 32 per cent. as  $\text{CO}_2$ ; silica, nil; carbon, the whole.

Assuming the following quantities to be taken for a charge: sand, 120 kilos.; sodium sulphate, 60; calcium carbonate, 39; coke, 3 kilos.; total, 222 kilos.; then the loss will be: on the sodium sulphate, 37.2; on the calcium carbonate, 17.49; coke, 3 kilos.; total, 58.14 kilos.; so that the yield of glass will be  $222 - 58 = 163.86$  kilos. (see this Journal, 1897, 43).—C. S.

*Plate Glass, Rough-Etching.* Sprechsaal, 29, [49], 1349.

BEFORE treating with hydrofluoric acid, the glass is rough-etched, by immersion in an acid bath, if the sheets are small. In the case of large sheets an edging of wax—prepared by incorporating  $\frac{1}{2}$  kilo. each of shoemakers' wax and beeswax, and 50 to 80 grms. of oil of turpentine—is carefully placed all round the part of the sheet to be treated, forming a trough to contain the etching fluid. The background and all portions of the sheet, except those to be occupied by the design, are coated with a preparation which must be sufficiently fluid to apply with the brush (or by lithography), and cover well without spreading, dry throughout in 6 or 8 hours, and resist the action of acids. The following mixtures answer well:—

	I. Thin.	II. Medium.	III. Thick.
	Grms.	Grms.	Grms.
Rectified oil of turpentine ..	1,000	1,000	1,200
Gum dammar.....	200	..	..
Venice turpentine .....	300	200	200
Powdered Syrian asphalt ...	600	500	500
Rosin.....	..	150	200
Burgundy pitch .....	..	150	..
Tallow .....	..	100	100
Beeswax.....	..	100	..

They are prepared by heating the materials over a sand-bath, taking precautions against boiling over. The product

is stored in closed vessels to prevent the evaporation of turpentine, which latter substance is also used for thinning down the (warmed) mass when required.

To apply the preparation, long, fine brushes of various sizes are used, the design, drawn on paper, being laid under the small sheets of glass, or indicated by laying the paper on the larger sized sheets, and dusting coloured powder through perforations made along the outline.—C. S.

**Clear Glass.** [*Materials.*] A. M. Spreehsaal, 29, [48], 1326.

In the production of clear glass, purity of materials, cleanliness, and care in the mixing and fusing of the constituents are of prime importance. Decoloration is effected either by the complementary colouring action of manganese and other oxides, or by oxidising agents, such as nitrate of soda and arsenic. The use of coloured cullet should, as far as possible, be avoided, and regularity as to purity of the materials should be secured.

The following proportions are recommended for the several grades of glass specified:—

(a.) *Lead Crystal for Sonorous Drinking Glasses and Finest Cut Ware.*—(Quartzsand, 100; potash (90 per cent.), 33·33; minium (free from iron or copper), 50; pulverised limestone, marble, calcspar, or Danish chalk, 8·66; nitre, 3·66; manganese oxide, 0·10 to 0·15; crystal cullet, 100 parts.

(b.) *Crystal for Fine Table-Ware.*—Quartzsand, 100; soda (90 per cent.), 35; minium, 8; nitre, 2; lime (as under a), 10; arsenic powder, 0·5; manganese oxide, 0·15 to 0·2; red cobalt oxide, 0·0066; crystal cullet, 100 parts.

(c.) *Semi-Crystal for Ordinary Ware.*—Quartzsand, 100; soda (90 per cent.), 33·5; lime (as above), 20; nitre, 2; arsenic powder, 0·5; manganese oxide, 0·2 to 0·25; red cobalt oxide, 0·001; semi-crystal cullet, 100 parts.

(d.) *Bohemian Crystal I.*—Quartzsand, 100; best potash, 35; calcined lime, 19 (or marble, &c., 26); nitre, 1·25; green nickel carbonate, 0·007 to 0·009; Bohemian crystal cullet, 100 parts.

(e.) *Bohemian Crystal II.*—(Quartzsand, 100; best potash, 25; soda (90 per cent.), 5; powdered marble, &c., 28; minium, 3·25; arsenic powder, 0·75; Bohemian crystal cullet II., 100 parts.

(f.) *Bohemian Crystal III. Hard Soda-Glass.*—Quartzsand, 100; best potash, 25; soda (90 per cent.), 10; powdered marble, &c., 25; arsenic powder, 1·5; nitre, 0·5; manganese oxide, 0·05; soda crystal cullet, 100 parts.

(g.) *Bohemian Crystal IV. Soft Soda-Glass.*—Quartzsand, 100; best potash, 20; soda (90 per cent.), 13·33; powdered marble, &c., 20; arsenic powder, 3; minium, 1; manganese oxide, 0·080 to 0·1; soft soda crystal cullet, 100 parts.

(h.) *Crystal Glass for Open Furnace with direct Wood Fire.*—Quartzsand, 100; molasses potash, 28; soda (90 per cent.), 4; powdered marble, &c., 24; nitre, 1; litharge, 2; green nickelous carbonate, 0·008 to 0·01; cullet from similar glass, 100 parts.

(i.) *Moulding Crystal.*—Same as a and b.

(k.) *American Moulding Crystal.*—Quartzsand, 100; soda (99 per cent.), 39; minium, 51; nitre, 3; calcined borax, 0·1; nickelous carbonate, 0·005 to 0·01; red cobaltous oxide, 0·0005; cullet from similar glass, about 100 parts.

(l.) *Ordinary Moulding Glass for Household Ware.*—Quartzsand, 100; soda (90 per cent.), 42; limestone, &c., 25; nitre, 2; arsenic powder, 0·5; calcined borax, 0·5; nickelous carbonate, 0·009 to 0·012; red cobaltous oxide, 0·0005 to 0·0007; cullet from similar glass, 100 parts.

(m.) *Plate Glass.*—Quartzsand, 100; soda (90 per cent.), 33·33; calcspar, &c., 30; nitre, 2; arsenic powder, 0·5; borax, 0·5; nickelous carbonate, 0·009 to 0·012; red cobaltous oxide, 0·0005 to 0·0008; plate glass cullet, 100 parts.—C. S.

**Enamels for Iron Plates, &c.** Claus. Berg- u. Hüttenm. Zeit. 1896, 55, 34.

The enamel consists of 130 parts of felspar, with 125 of borax, 70 of quartz, 25 of soda, 17 of nitre, 10 of fluorspar,

4 of antimony, and 0·5 of cobalt. The large proportion of felspar makes the enamel less fusible, but it adds to its covering power and to its resistance to chemical action.

—W. G. M.

**Glazes and Enamels, Part played by Boric Acid in.**

L. Grenet. Comptes rend. 123, [21], 891–893.

The coefficient of expansion of a glaze or enamel is sometimes increased by the addition of boric acid, and, on the other hand, is sometimes diminished, although the coefficient of expansion of boric acid itself is greater than that of any glass. The author finds that if boric acid be used in successively increased quantities, the first effect is to lower the coefficient, and afterwards to progressively increase it. This result appears to be connected with the circumstance that if the proportion of bases be large, devitrification occurs; whereas if the proportion of boric acid be large, a separation of nearly pure boric acid takes place.—V. C.

**PATENT.**

*Improved Kiln for "Firing" Colours, Gold, Enamels, and the like, on all Kinds of Pottery and Glass; applicable also to other Purposes, such as Baking Bread and the like.* D. Chapman and W. Illiworth, Longton. Eng. Pat. 23,831, Dec. 12, 1895.

The articles are placed on a frame, which revolves so as to carry the articles to be fired into the furnace while withdrawing from the heated chamber, the articles which have been fired. The inventors claim improved construction of kiln and means of securing continuous firing.—V. C.

**IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.**

*Slag Bricks, Manufacture of.* Berg- u. Hüttenm. Zeit. 1896, 55, 340.

BLAST-FURNACE slag is too brittle and too sharp-cornered for road-metal; and if the hot slag, whilst still pasty, is worked in a brick press, the moulds are not properly filled, and the resulting slag block becomes brittle, like quickly cooled glass. At the Karl Emil-Hütte in Königshof (Bohemia), bricks are made from the cinder produced in a coke furnace smelting an oolitic impure clay ironstone. The slag, having the percentage composition of from 25·8–27 SiO<sub>2</sub>, 1·5–1·7 FeO, 17·3–19·3 Al<sub>2</sub>O<sub>3</sub>, 51·5 CaO, 0·4–2·5 MgO, and 1·3–1·8 S, is run from the cinder-notch into water, where it is granulated to a clear grey-coloured sand. It is then mixed in a mill with milk of lime and pressed into bricks, which must be left for eight days to harden before they will bear transport. The bricks should contain about 26·5 SiO<sub>2</sub>, 17 Al<sub>2</sub>O<sub>3</sub>, and 52 CaO per cent., and should bear a pressure of 18 kilos. per sq. cm. (256 lb. per sq. in.), though they are only guaranteed to carry two-thirds of this amount. The whole width of the brick should withstand a load of 4,870 kilos. (nearly 5 tons). Another furnace, producing a slag of the composition 33 SiO<sub>2</sub>, 1 FeO, 4 $\frac{1}{2}$  MnO, 18 $\frac{3}{4}$  Al<sub>2</sub>O<sub>3</sub>, 40 CaO, 2 $\frac{1}{2}$  MgO, and 1 $\frac{1}{2}$  S per cent., gives less satisfactory bricks, that will not bear transport for three months.

—W. G. M.

*Limestones, Estimation of Iron and Alumina in.* Désiré de Paepé. Chem. Zeit. 1896, 20, 1004.

See under XXIII., page 163.

**PATENTS.**

*Burning Cement-making Materials, Lime, Chalk, and the like; Impts. in Apparatus for, and the Obtainment therefrom of Carbonic Acid Gas.* W. R. Taylor, Rochester. Eng. Pat. 68, Jan. 1, 1896.

The inventor claims the obtaining from the above materials of practically pure carbonic acid gas, and the combination in apparatus therefor of "a drying floor on which wet slurry is partially dried, a bed of retorts in which the remaining moisture and carbonic acid is driven off from the material, and a fusing kiln in which the dried material is burnt or fused."—V. C.

*Artificial Stone, A New or Improved Manufacture of, for Building, Decorative, and other Purposes.* F. W. Maxwell and W. Beer, Manchester. Eng. Pat. 2614, Feb. 5, 1896.

A MATERIAL produced by admixture of a stone base with oxide of magnesium, and successive treatment with magnesium chloride, oleate soap, and acetate of aluminium.

—V. C.

*Veined, Coloured Marble; Improved Process for Producing Artificial* M. Bernstein, Berlin. Eng. Pat. 17,281, Aug. 5, 1896.

THE material consists mainly of the waste produced in polishing stones, which is mixed with a binding material, such as a mixture of magnesite and magnesium chloride, and allowed to harden under slight pressure. In order to produce veins, "the colouring matters are previously mixed with the suitable quantity of pulverised white marble and brought into the fundamental mass in this mixed state."

—V. C.

*Artificial Stone, Impts. in the Manufacture of.* A. Cléry, London. Eng. Pat. 24,212, Oct. 30, 1896.

A PLASTIC material, hardening to the consistency of stone, suitable for application to and protection of stony surfaces. The plastic material is prepared by adding about one part of the following liquid mixture, viz., zinc 35 per cent. and hydrochloric acid 65 per cent., to three parts of a mixture composed of about 30 per cent. of zinc oxide mixed with sandstone, Portland stone, sand and marble, or granite.

—V. C.

*Piles and the like, Impts. in, and in Means for Protecting them from Water Insects, and Preserving them generally.* H. Gallinowsky, Longbeach, Miss., U.S. Eng. Pat. 25,851, Nov. 17, 1896

A FIBROUS material, such as jute, is soaked with boric acid, magnesium chloride, hydrated magnesium oxide, and sal ammoniac, and wrapped round that portion of the pile which is to be immersed in water, which portion has a diminished cross section, and the whole is then subjected to a creosote bath.—V. C.

## X.—METALLURGY.

*Calcium Carbide: A New Reducing Agent.*

H. N. Warren. Chem. News, 1897, 75, 2.

THE author gives the results of a series of experiments in which calcium carbide was used as a metallurgical reducing agent.

An excess of litharge, when heated to redness in contact with calcium carbide in a clay crucible, was reduced, with formation of metallic lead and calcium oxide, CaO, the reaction being accompanied by vivid incandescence.

On heating a mixture, in which the proportion of carbide exceeded that of the litharge, to various temperatures, alloys of calcium and lead of varying composition were obtained, together with the expulsion of carbon dioxide. The alloys thus formed are all more or less brittle, their melting point ranking below that of pure lead, and are slowly but completely decomposed in contact with aqueous vapour. Stannic oxide, cupric oxide, and also ferric oxide, at correspondingly higher temperatures, were readily reduced, yielding results of no practical value; in the case of the cupric alloys, those samples containing less than 1 per cent. of calcium being rendered cold-short, and breaking under very small strain, whilst iron containing calcium approaches in appearance that of ferro-manganese, being even more brittle and very oxidisable in contact with water. Oxides of manganese, nickel, cobalt, and even chromium, molybdenum, and tungsten were also readily reduced, yielding calcium alloys.—A. S.

*Iron Carbide, Pure.* E. D. Campbell. Amer. Chem. J. 1896, 18, 836—847.

CAREFULLY annealed bars of crucible cast steel (1.29 per cent. of C) were suspended from a copper ring in a 4 per cent. solution of hydrochloric acid. The ring was connected

to the positive pole of a series of storage cells, a platinum cup being cathode, and an electric current of 1 ampere at 8 volts, passed through for 45—16 hours. Each day the deposit on the strips was brushed off and collected, and the process renewed. From 576 grms. of steel which was dissolved, 55 grms. of carbide was collected, or 9.66 per cent., or about half the total carbon in the steel (assuming the formula of the carbide to be Fe<sub>3</sub>C). The carbide obtained consists of minute bright steel-grey scales of sp. gr. 6.944, gradually but completely converted by moist air into carbon and ferric oxide, and completely soluble in moderately strong hydrochloric acid. Analyses of the body gave 6.646 and 6.625 per cent. of carbon; Fe<sub>3</sub>C requires 6.67 per cent.

The gases arising from the solution of the carbide in hydrochloric acid were examined. About 150 c.c. of gas was yielded by 0.600 gm. of the carbide. Determinations were made of the olefines (by absorption with bromine), the carbon dioxide formed by explosion, first of the original gas and then of the gas without olefines, and the hydrogen (by absorption with palladium chloride). Calculated on 1 gm. of the carbide, the average result was: volume of gas, 250 c.c.; hydrogen, 210 c.c.; olefines, 9.6 c.c.; total CO<sub>2</sub>, 72 c.c.; CO<sub>2</sub> from paraffins, 33 c.c.; CO<sub>2</sub> from olefines (by difference), 39 c.c. The figures show that about 60 per cent. of the total carbon of the carbide appears in the gases, the rest clearly occurring as some hydrocarbon which either condensed or remained in solution. The liquid in the flask smelt strongly of butane, in which form no doubt most of the missing carbon existed. The ratio of the volume of the olefines to that of the CO<sub>2</sub> they produced shows that butylene must have been present in quantity. The author suggests that these iron carbides have the general formula C<sub>n</sub>Fe<sub>m</sub>, being olefines in which H is substituted by —Fe. Fe. Fe—; when these are dissolved, the corresponding olefine is formed, which partly polymerises and partly picks up hydrogen, which is simultaneously formed by the action of the iron group on the acid.

—J. T. D.

*Carbide in Steel.* F. Mylius, F. Foerster, and G. Schoene. Zeits. anorg. Chem. 1896, 13, 33.

THE results arrived at by the authors are as follows:—(1.) Ignited steel is a mixture of crystallised iron and crystallised iron carbide. (2.) Iron carbide is a definite compound of the composition CFe<sub>3</sub>, and resembles and is analogous to manganese carbide, CMn<sub>3</sub>, but is more indifferent to solvents. (3.) Iron carbide, is not altogether insoluble in dilute acids. (4.) Iron carbide dissociates on strong heating into carbon, and iron poorer in carbon, and from this latter iron carbide again separates on slow cooling. (5.) Iron carbide enters into chemical reaction with iron at a bright red heat.—L. T. F.

*Gold, Cyanide Process: Comparison of Zinc and Electrical Methods of Precipitation.* A. von Gernot. Johannesburg Chem. and Metall. Soc., Oct. 1896.

THE most important points for comparison are the relative strengths of solution and consumption of cyanide in the two processes. In regard to the former, the solution of gold depends more upon mechanical conditions than upon strength of solution, as even a 0.05 per cent. solution contains over 88 times the amount of cyanide actually required. A 0.3 per cent. solution is used on the Rand because, although the gold might be dissolved in a weaker liquor, the zinc would fail to precipitate it. Thus, in the zinc process, the strength of solution must be adapted to the precipitant, whilst in the electrolytic process any strength may be used according to the nature of the ore to be treated. The crudeness of the zinc method is one of its prominent faults, great care being needed in a clean-up, and no means being available for checking loss. "Then, taking zinc cyanide bullion as averaging 70 per cent. fine gold, and Siemens-Balske cupelled bullion as 89 per cent., each oz. of fine gold in the latter case is worth 6d. more than in the former." The cost of electrical precipitation for a plant capable of working 500 tons per diem may be taken at (per ton):—Filling, 10d.; cyanide, 3.4d.; lime, 0.5d.; white labour, 5d.; native labour, 1.9d.;

fuel and power, 4*d.*; lead, 1.5*d.*; iron, 0.3*d.*; charge due extra cost plant, 0.5*d.*; store and general charge, 3.2*d.* Total, 2*s.* 6.3*d.* For a 7,000-ton plant, four boxes 4½ ft. × 3 ft. × 30 ft. would be used, containing 3 tons of iron per box.

*Treatment of Slimes.*—For this purpose the electrical process has no rival. It is now for the first time possible to treat all ore products—free gold, concentrates, tailings, and slimes; and since the last-named may now be treated separately, there is no need to leave as much pulp as possible in the tailings vat, with the risk of rendering the sands slimy and unleachable. Only the leachable portion of the mill-pulp will be retained, and extractions should therefore be higher. Early in 1897, plant, capable of treating over 50,000 tons of slimes monthly, will be at work, and such a plant will soon be a necessary part of every mill. At present every ton of water introduced into the stock cyanide solution in the tailings necessitates the waste of an equal volume of dilute solution to make way for it in the tanks. The gold and cyanide in this solution were formerly lost, but they will now be recovered by applying this solution to the treatment of slimes, for which a very dilute liquor is appropriate. In a slimes plant the pumping and precipitating capacity must be very great, since 7 tons of solution are handled for each ton of slimes treated. The precipitation must be very perfect, since the dilute liquor displaced, bulk for bulk, by the slimes under treatment, must run to waste, and any gold and cyanide left in it is lost. The rate at which the slimes settle depends upon their nature, upon the depth of the vat, upon the ratio of slimes to solution in the mixture, and upon the influence of the agents (such as lime) added to accelerate settling. The treatment of slimes fresh from the mill, causes difficulty owing to the ready solubility of the gold; this happens through some of the gold in the overflowing slimes from a newly charged vat being dissolved by the agency of a little cyanide left in the vat after discharging. Old slimes from slimes dams give trouble owing to the presence of sulphates and free acids from oxidised pyrites, and from decomposed animal and greasy matter from the mine and the mill. These complications are not observed in laboratory trials, but only in actual working. The whole may be summed up by saying that while zinc has in its day done good service, it no longer meets modern requirements, and must be superseded by electricity.—W. G. M.

*Silver, Extraction of.* [*Treatment of Sulphides with Sulphuric Acid.*] P. Truchot. *Revue Chim. Ind.* 7, [84], 380—383.

In the extraction of silver by the Russell process in the United States, a double hyposulphite (thiosulphate) of sodium and copper is employed, and this solution gives much better extractions than hyposulphite of sodium alone. The drawback of the process was the difficulty of treating the sulphide precipitate, which takes the form of a dry powder, difficult to handle, causing loss and being difficult to sample and assay. The following successful method of treatment has been adopted at the Marsac Mine of the Dewey-Walter Refining Co.:—

A charge of about 150 kilos. of the sulphide precipitate and 450 kilos. of sulphuric acid of 66° B. is placed in an iron pot, carefully stirred, and heated to boiling. Sulphur dioxide, mixed with sulphur, is violently disengaged at first. The reaction may be hastened by means of a jet of steam. When the mixture begins to get pasty, about 1,350 kilos. of acid are added in quantities of 15 kilos. at a time. As the boiling proceeds, the precipitation of granular insoluble sulphate of copper necessitates frequent stirring. The pots are not rapidly attacked, nine having been employed during 1894. After about an hour's violent boiling, the operation is stopped and the charge allowed to cool, after which it is led into the dissolving vat, containing water, and boiled by a jet of steam, and filtered. Almost all the copper is contained in the first liquid. The heavy white mud is washed with weakly acid solutions to remove the silver; after washing, it contains about 5 to 19 ozs. of silver and 50 to 100 ozs. of gold per ton, and consists principally of sulphate of lead, and is smelted directly. The solutions are passed through a filter of washed quartz sand, upon

which and in the dissolving vat considerable quantities of metallic silver are deposited; about 10,000 ozs. of silver per year accumulate on the filters. The filtered liquors are heated by steam in a vessel containing copper (usually electrolytic cathodes), with a current of air passing over, about 4 to 18 hours being required for the precipitation. After 20,000 ozs. of silver have accumulated in the vat, it is transferred to a special vat and washed with cold water and cold acidulated water till no further trace of copper is found in the washings; this operation takes 15 hours. The silver is dried, pressed into cakes, again dried, and melted under borax as usual. The sulphate of copper is recovered from the liquors by crystallisation.

A foreman and three men are able to work a plant capable of treating over 52,000 kilos. of the sulphides per annum.—H. B.

*Cadmium with Silver and Copper Metallic Combinations.* A New Mode of Alloys of. J. B. Senderens. *Bull. Soc. Chim.* 15, [24], 1241—1247.

A bar of cadmium, placed in a solution of sulphate or acetate of silver, precipitates the latter metal, but if the action be allowed to go on for a long time, the loss in weight of the bar of cadmium is much more than equivalent to the silver precipitated, and as this excess was not present in the solution, it was found in the metallic deposit, which had been slowly transformed into a very oxidisable alloy of the formula  $\text{AgCd}_2$ . Similar experiments were tried with solutions of chloride, sulphate and acetate of copper. Pulverulent alloys were formed, but containing less cadmium.—G. H. B.

*Steel, Alloys of, with Molybdenum and Chromium.* Oesterr. Zeits. Berg- u. Hüttenw. 1896, 54, 590.

THE Schneider Company at Crensat have lately experimented with regard to the production of molybdenum-chrome steel for armour plates. They find that the addition of 0.2—0.3 per cent. of chromium and a like amount of molybdenum to steel greatly increases its resistance to penetration, without rendering it brittle. This steel may be made in the converter or in the crucible, with the aid of ferro-chrome and of pure metallic or of alloyed molybdenum. It may be forged, rolled, hardened, or cemented.—W. G. M.

*Tellurium Production at the Royal Hungarian Lead and Silver Smelting Works at Schemnitz.* J. Farbaký. *Zeits. f. angew. Chem.* 1897, 11.

It has long been known that the presence of tellurium gives rise, by volatilisation, to a loss of gold and silver during their cupellation. Experiments made with the object of removing tellurium from the gold and silver obtained at the Pertuzola works in Italy were published last year by C. and F. Heberlein (*Berg- und Hüttenm. Zeit.*), and C. Whitehead (this Journal, 1896, 202) has worked out a process for separating tellurium from the silver and copper contained in the silver mud formed in copper electrolysis. Applications of tellurium in medicine, porcelain painting, and thermo-electricity are heard of from time to time, but it would appear that so far no satisfactory results have been obtained, and that tellurium is at present only valuable on account of its rarity. Partly in the hope that by making tellurium more accessible some practical applications of it will be discovered, it has been decided to manufacture it at Schemnitz from the Siebenbürgen ore used there. The ores used contain calcium and magnesium carbonates, silica, lead, copper, and zinc compounds, and gold, silver, and tellurium. The ore is first dissolved, as far as possible, in concentrated sulphuric acid; the mass is then extracted with hot dilute hydrochloric acid, and filtered. The residue contains all the gold and silver, the filtrate the tellurium. The latter is precipitated by saturating the liquid containing it with sulphur dioxide, which is employed in the liquefied form. The precipitated tellurium is washed, dried, and finally fused and cast in sticks or granulated. It contains from 72 to 85 per cent. of tellurium, the principal impurities being copper and tellurium dioxide, the latter formed by the oxidation of the finely divided metal during the drying process.—T. E.

*Cobalt and Nickel Sulphides of.* G. Chesneau. Comptes rend. 1896, **123**, 1068—1071.

ALKALINE polysulphides saturated with sulphur, give with cobalt salts a black persulphide,  $\text{CO}_2\text{S}_2$ , insoluble in alkali monosulphides, but soluble in sulphides saturated with sulphur. Nickel salts give a corresponding persulphide, which, however, is soluble in alkali monosulphides, but only with difficulty in polysulphides.—J. T. D.

*Tungsten, The Reduction of, from Wolfram by Carbon in the Electric Furnace.* E. Defacqz. Comptes rend. 1896, **123**, 1288.

WOLFRAM from Zinnwald, in Bohemia, was used in the experiments. It contained about 72 per cent. of tungstic acid, and about 16 per cent. of manganous oxide, the remainder consisting of ferrous oxide, lime, and silica in variable proportions. A mixture of the mineral with sugar carbon, subjected to the action of an electric arc of 1,600 amperes and 60 volts for 12 minutes, gave a melted metallic mass, easily detachable from the scoria. Analysis of the tungsten thus obtained showed it to be entirely free from manganese and calcium, the only impurities being about 5 per cent. of carbon, rather more than 2 per cent. of iron, and 0.5 per cent. of silicon. The author concludes that the direct treatment of native minerals in the electric furnace is capable of yielding metals sufficiently pure for industrial application.—E. S.

## PATENTS.

*White Arsenic, Impts. in the Manufacture of.* T. P. Sims and W. Terrill, Swansea. Eng. Pat. 9076, April 30, 1896.

See under VII., page 142.

*Galvanising, An Impt. in. [Tinning.]* R. Heathfield and W. S. Rawson, London. Eng. Pat. 24,703, Dec. 24, 1895.

ANY imperfection in the coating of galvanised iron or steel articles may be remedied by cleansing them from all traces of oxide, and then immersing in a bath composed of about 2 parts of chloride of tin (fused), and 10 parts pyrophosphate of soda to 600 parts of water. To prevent too rapid deposition of tin, the bath is preferably started cold and then gradually raised to boiling point. An immersion of about 30 minutes suffices to give a coating of tin to the bare iron surfaces as well as to the galvanised portions, but if the articles are to receive a second coating in the zinc-depositing vat, a 10 minutes' immersion in the tin bath will suffice.—G. H. R.

*Treatment of Iron and Steel, and Production of Alloys [producing Chromated Iron or Steel]; Impts. in the.* E. Pfaet, Paris. Eng. Pat. 203, Jan. 3, 1896.

CHROMIUM is deposited upon bars or tubes of iron or steel by electrolysis, and the bars or tubes are afterwards either melted, hammered, rolled, drawn, or subjected to cementation.—R. S.

*Auriferous Antimony and other Ores, Smelting; Impts. in Plant and Process for.* C. C. Longridge, Leigh, and G. T. Holloway, London. Eng. Pat. 303, Jan. 4, 1896.

AT least four furnaces are arranged in cascade form, one above the other; in the first, antimony sulphide ores are liquated; the second is for reducing, the third for refining, and the fourth for "starring." For the extraction of gold from antimony ores an extra furnace for mixing is introduced between the first and second. The refining and starring may both be conducted in the third furnace if desired. The last three furnaces are separately fired with gas, and the products of combustion may be used to fire the mixing and liquating furnaces. In applying the process, the auriferous antimony ore is liquated, and is run through a launder into the mixing furnace, in which it is agitated with about half its weight of fused metallic antimony until all the gold has alloyed with the metal. The agitation is effected by rotating the mixing furnace, which is made in the form of a horizontal cylinder mounted on rollers. The sulphide is then run on to the other furnaces, but the antimony is used to treat three other batches of ore, or until it assays about 100 ozs. to the ton. In other cases the ore is treated with so much metallic iron that the reduced antimony is in quantity sufficient to dissolve the gold from the whole charge of ore, and the mixture is rotated as before. In treating other gold-bearing substances, the material is first mixed with fused antimony sulphide, which dissolves the gold, and then the auriferous sulphide is agitated with antimony as above.—W. G. M.

*Gold, Amalgamation of, and of like Metals; Improved Apparatus for effecting.* E. L. Oppermann, London. Eng. Pat. 1469, Jan. 21, 1896.

MERCURY vapour generated in a closed retort is injected, with steam at a suitable pressure, into shallow covered channels, through which the ore is passing from the stamps, or from a rotating mixer into which steam may be injected if desired. From the closed channel, the ore passes over amalgamated plates to a rotating separator provided with electrodes. The amalgamated plates themselves, and rods supported at a short distance above them, also form electrodes to the liquid passing between them. Ammonia or other gases may be injected in addition to the steam and mercury vapour. The apparatus is especially designed to carry out the process specified in Eng. Pat. 17,020 of 1895 (this Journal, 1896, 120).—W. G. M.

*Gold, Impts. in Apparatus for Use in the Extraction of, from Auriferous Material by the Aid of Chemical Solvents.* J. Y. Johnson, London. From J. J. Deeble, Bendigo, Victoria. Eng. Pat. 23,954, Oct. 27, 1896.

THE vat for extraction is fitted with rotating horizontal agitators mounted on a vertical shaft, so that their direction of rotation may be reversed, or their position may be altered, by raising or lowering the whole shaft by means of a rack and pinion or other contrivance, operated from a platform above the vat. A sluice-valve is arranged for drawing off the solution from any level in the vat, and a waste-discharge valve is provided at the lowest level for the removal of the extracted ore. The inner surface of the vat has projecting pieces, which should produce eddies during the rotation.

—W. G. M.

*Steel, Impts. in the Production of, and in the Refining of Iron Ore.* H. H. Lake, London. From H. Schweitzer, New York, and E. Lungwitz, Brooklyn. Eng. Pat. Aug. 18, 1896.

CALCIUM earbide is introduced into the Bessemer converter, either at first or (preferably) some time after the commencement of the blow. The objects of the addition are:

the removal of phosphorus and sulphur from the metal by by means of lime in *statu nascendi* acting upon the anhydrides of the metalloids, aided by the thorough mixture of the calcium carbide and iron; the production of a higher temperature in the converter by the formation of CaO from  $\text{CaC}_2$ ; and the carburisation of the steel by the carbon of the carbide.—W. G. M.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### (A.)—ELECTRO-CHEMISTRY.

*Analytical Chemistry. The Importance in, of the Ionic Dissociation Theory of Arrhenius.* F. W. Küster. Zeits. f. Elektrochem. **3**, (1896), 233—236 and 257—260.

ANALYTICAL chemistry can boast of a large and increasing literature; but considered purely as a science it cannot be rated very highly. Until recently, indeed, we were not in possession of such genuine views and theories as were necessary for its development on broad scientific lines. But recently the position has improved. The theory of solutions and the law of mass-action have enabled us to investigate the conditions of equilibrium in solutions. We have a better knowledge of the nature of salt solutions and of reactions between salts, and it is now possible to develop a theory of analytical reactions. With rare exceptions the analytical chemist has to deal with aqueous solutions of salts (including, of course, acids and alkalis). These differ entirely in their physical behaviour and properties from other solutions. Arrhenius has explained this by the hypothesis that on solution in water, salts are split up more or less completely into electrically charged atoms or groups of atoms. This also explains why such solutions differ from all others in being relatively good conductors of electricity. Arrhenius' theory affords an explanation of many chemical as well as physical phenomena. Consider, for example, the remarkable fact that there are no specific reactions for salts in aqueous solution. The reactions exhibited by common salt are not peculiar to it alone. Part of them are shared by  $\text{KCl}$ ,  $\text{BaCl}_2$ ,  $\text{FeCl}_2$ , and other chlorides; others are exhibited by other salts of sodium. Compare with this the fact that solutions of substances like sugar, naphthalene, azo-benzene, &c., which are not salts, do exhibit specific reactions. The difference in behaviour becomes intelligible if we assume with Arrhenius that when common salt is dissolved in water the solution contains little or no salt, but only the products of its dissociation—the ions  $\text{Na}$  and  $\text{Cl}$ . Suppose that we have in analytical chemistry to deal with 50 cations and 50 anions. These would give us 2,500 simple salts. If these behaved as salts in their solutions they would exhibit 2,500 different reactions. Arrhenius' theory explains why we have actually to deal with only the reactions of 50 cations and 50 anions, or 100 altogether.

Again, consider the reactions of the compounds—

and—

Those of the first group exhibit certain definite reactions, of which that with barium chloride is specially characteristic. Those of the second group are derived from sulphuric acid in the same manner (by replacement of hydrogen), but they do not exhibit any common reaction. On Arrhenius' theory this difference in behaviour offers no difficulty. When the compounds of the first group suffer electrolytic

dissociation they produce different cations; but they all produce the same anion,  $\text{SO}_4''$ , and hence all exhibit the reactions of this anion. The compounds of the second group behave quite differently when dissolved in water. The last three are non-conductors; in solution they do not split up into ions. The first three behave as conductors; but the constituents which are attracted towards the anode are not the ions  $\text{SO}_4''$ , but the monovalent groups  $\text{CH}_3-\text{SO}_4'$ ,  $\text{C}_2\text{H}_5-\text{SO}_4'$ , and  $\text{C}_6\text{H}_5-\text{SO}_4'$ . No single one of the six derivatives produces the sulphuric acid anion  $\text{SO}_4''$ ; hence we cannot expect any one of them to exhibit the reactions of this ion. Furthermore, as all six produce either different anions, or none at all, they naturally have no common reaction.

We must refer to the original paper for the explanation according to Arrhenius' theory of other phenomena and reactions, among which the following may be mentioned:—(1.) The precipitation (or non-precipitation) of metals in the presence of certain salts; e.g., Why are silver salts not precipitated by sulphuretted hydrogen when excess of potassium cyanide is present? (2.) The classification of acids and bases as "strong" and "weak." (3.) The influence of the presence of salts in solutions of the corresponding acids. Here the precipitation of iron from solutions of its acetate is discussed, and the effects of adding acetic acid and sodium acetate are explained. (4.) How the delicacy of methyl orange as an indicator for a particular acid is affected by the presence of a neutral salt of this acid.

—D. E. J.

### *Electrolysis of Salts and Bases in Presence of Ammonia.*

S. M. Losantsch and Z. Jovitschitsch. Mitteil. d. königl. Serb. Akad. d. Wiss. (Ber. **29**, 2436—2438.)

WHEN alkali salts are electrolysed in presence of ammonia so that the cation sets free hydrogen, and the anion (by reacting on the ammonia) nitrogen, the amount of nitrogen liberated is relatively too small. The authors have examined the causes of this irregularity, using graphite anodes and platinum cathodes. Electrolysis of  $\text{NaCl}$  with  $\text{NH}_4\text{OH}$  gave too little nitrogen by 10 per cent. After the electrolysis, hypochlorite was found to be present, and also chloride of nitrogen. The authors believe that the hypochlorite is formed directly, as when chlorine-water reacts on ammonia. When the hypochlorite has attained a certain concentration it forms with the ammonia, chloride of nitrogen; this again reacts upon the ammonia, and nitrogen is set free. The amount of decomposed hypochlorite depends upon the concentration and temperature, increasing as the temperature falls, and the solution becomes weaker in  $\text{NH}_3$ . At a certain concentration and temperature, the amount of nitrogen evolved should be strictly equivalent. (This was verified by experiment. Solution,  $\text{NaCl}:\text{NH}_3 = 9:1$ . Temperature,  $100^\circ$ .)

When  $\text{KBr}$ ,  $\text{KI}$ , and  $\text{KF}$  are electrolysed in presence of ammonia, hypobromite, hypiodite, and iodide of nitrogen are found to be formed. No hypofluorite or bromide or fluoride of nitrogen could be detected. Hence the non-equivalence in the electrolysis of  $\text{KF}$  must be due to the fluorine acting upon the electrode. When  $\text{KOH}$  and  $\text{K}_2\text{SO}_4$  are electrolysed, part of the oxygen developed is set free as such, and the rest goes to form nitrites and to set free nitrogen. Other examples of a similar action of nascent oxygen are given.—D. E. J.

### PATENTS.

*Electrolytic Apparatus, Impts. in.* [Rotating Depositing Barrel.] R. Heathfield and W. S. Rawson, London. Eng. Pat. 25,002, Dec. 31, 1895.

IN lieu of wood, the staves of barrels described in Eng. Pat. 5537, 1894 (this Journal, 1895, 756), are made of Portland cement, strengthened with an iron framework consisting of two parallel bars, and cross bars, between which bolts are passed to fix the staves to the ends of the barrel. The conductors are tubes or angle-bars sunk in the cement, so as to present only a small part of their surface on the inside of the barrel, and their ends are flattened and soldered to metal sockets moulded into the cement, and covered with a rubber sleeve, over which the sleeve of the lead-wire can

be drawn, so as to form a water-tight joint. Slots to admit the electrolyte are provided in the staves, and are covered with wire gauze on the outside, and formed with one side sloping and the other abrupt, so that the articles to be galvanised may not fall on the gauze. The barrel may be divided into compartments by inwardly-projecting rings, and the conductors divided into sections connected by plugs, so that they may be used independently. Where it is undesirable to cover the anode with a louver, a cut-out is provided in case of a short circuit. This consists of an electro-magnet which, while the normal current is passing, attracts a lever having at its other end two prongs. On a short circuit occurring, these dip into two mercury cups, close the external circuit, and cut out the barrel. By means of a similar lever, the circuit through the barrel is closed automatically when the latter is lowered into the bath.

—G. H. R.

*Chloride Solutions for Disinfecting and like Purposes. An Impt. in the Preparation of Electrolysed.* E. Hermite, E. J. Paterson, and C. F. Cooper, London. Eng. Pat. 2197, Jan. 30, 1896.

See under VII., page 112.

*Filaments for Electric Incandescent Lamps. Impts. relating to Treating or Flashing.* [Organic Borates.] J. H. Douglas-Willan and F. E. W. Bowen, London. Eng. Pat. 3213, Feb. 12, 1896.

THE filaments are given a coating of carbon and boric anhydride by flashing them in an atmosphere of certain organic compounds containing both boron and oxygen, such as the borate of the alkalis, to which from 1 to 2 per cent. of ethyl iodide is preferably added, to lower the vaporising point.—G. H. R.

*Waterproofing, A New or Improved Process of Electrically Treating Various Materials [Silk, Cotton, or other Fabrics] for the Purpose of.* C. M. White, London. From The Electro-Waterproofing and Dye Fixing Company, New York, U.S.A. Eng. Pat. 8323, April 21, 1896.

THE silk, cotton, or other fabric to be waterproofed is moistened with water from the ordinary town supply, and subjected to electrolysis between an oxidisable anode and any suitable cathode, which are made to press on one another in any convenient way. The anodes are preferably composed of aluminium or tin, antimony and bismuth being unsuitable for the purpose. The electrodes may be of any shape, provided they bear accurately on the fabric throughout its surface, and the electrolysis must not be continued long enough to cause the reduction of the oxide first formed on the material, or the goods will not be waterproofed. The time required may vary between 1 and 30 seconds; and to render the process less delicate it is advantageous to cover the negative roller or plate with cotton-cloth, in order to absorb the hydrogen evolved.—G. H. R.

#### (B.)—ELECTRO-METALLURGY.

*Gold from Cyanide Solutions, Electrolytic Precipitation of.* S. Creasdale. Eng. and Mining J. 1896, 62, [24], 557—558.

THE author, after a large number of experiments conducted on a commercial scale, came to the conclusion that the most advantageous method for the recovery of gold from cyanide solutions was electrolytic precipitation, using amalgamated zinc plates for the positive electrodes and sheet lead for the negative electrodes. Zinc was chosen on account of its efficacy in precipitating gold from cyanide solutions, and its price not placing it beyond a commercial possibility. The strength of current used was 0.04 to 0.05 ampère per square foot of depositing surface. The voltage was not determined, but was very low. The flow of solution through the precipitating tanks was such that each square foot of depositing surface received the gold from  $\frac{1}{2}$  lb. of solution in 30 seconds. In three experiments the gold extraction was respectively 95.50, 99.56, and 99.06 per cent., and experience proved that these results could be obtained day after day without difficulty. With "lean" solutions,

the flow of solution through the tanks was doubled, and an extraction of 93.48 per cent. was obtained. The zinc plates at the end of the experiments showed little or no wear. The destruction or loss of cyanide in the experiments referred to was as follows:—(1) 8.78 per cent.; (2) 2.60 per cent.; (3) and (4) none. The cyanide solution as it came from the precipitating tanks was remarkably active in dissolving gold, due no doubt to the presence of nascent oxygen, which makes it especially valuable for treating the next lot of ore in the leaching vats. This increased solvent action was fully as great as that produced by the addition of sodium peroxide, &c. to ordinary cyanide solutions, whilst the destruction of cyanide was apparently not so great.—A. S.

*Gold Milling, Electricity in.* H. M. Chance. Proc. of the Eng. Club of Philadelphia, 1896, 13, [3], 214—218.

METHODS by which it has been proposed to use electricity in the extraction of gold are classified into—

1. *Electro-Magnetic*, in which a magnet is used to separate iron and other magnetic materials from particles of gold. Such methods have never been of practical importance.

2. *Electro-Solvent*, in which the ore, crushed or whole, is immersed in some solvent of gold (chlorine, potassium cyanide), through which an electric current passes. No process based on this idea seems to be actually at work.

3. *Electro-Amalgamating*, in which a current of electricity is passed from some part of the crushing apparatus through the water to the amalgamating plates or mercury pots, with the idea of aiding the amalgamation. This seems to be more or less effectual in keeping the amalgamating surfaces bright and preventing "sickening"; in one instance where such a process was applied to tailings, a considerable saving of gold was effected.

4. *Electro-Precipitating*, in which the gold, having been got into solution by chemical means, is deposited electrolytically. In the Siemens-Halske process, largely used in South Africa, the anodes are cast-iron plates and the cathodes sheet lead, arranged as baffle plates in a trough through which the solution slowly flows. When sufficiently coated the cathodes are melted and the gold expelled. With 8,000 sq. ft. of cathode surface, 100 tons of solution can be dealt with in 24 hours.

5. *Electro-Inductional*, in which high-frequency alternating currents are employed, with the idea of causing electric attractions between the particles of gold in ores which contain the metal in grains. No application of this on the large scale appears to have yet been made.

6. *Electro-Smelting*.—This does not appear to have been put in practice to any extent, no doubt because it is more expensive than the ordinary smelting processes.

That more successful applications of electricity to gold extraction have not been made, is probably due to the fact that electricians who have worked in this field have not had a sufficiently intimate acquaintance with the conditions of gold-milling practice.—J. T. D.

*Uranium, The Electrical Preparation of.* H. Moissan. Ann. de Chim. et de Phys., Oct. 1896.

THE author obtained uranium by heating in the electric furnace a mixture of the oxide with sugar carbon. The oxide was prepared by heating nitrate of uranium. In 12 mins. a button of uranium weighing 200 to 220 grms. was obtained. The proportion of carbon in the cast metal varied according as the oxide or the carbon predominated in the mixture.

It was found that under the following conditions, if the heating were carefully carried out, the metal could be prepared containing little or no carbon. About 500 grms. of a mixture of 500 parts of oxide of uranium with 40 parts of sugar carbon was placed in a carbon crucible and heated in the electric furnace with a current of 800 ampères at 45 volts. A fused ingot weighing 350 grms. was obtained. If the mixture be heated too long, the metal carbonises very easily, and eventually a crystallised carbide,  $C_3U_2$ , is formed. To prevent the action of nitrogen, the experiments are best made in a carbon tube closed at one end.

The author also obtained metallic uranium by electrolysis of the fused double chloride of uranium and sodium. The salt, which is kept fused by the calorific action of the current, was placed in a cylindrical porcelain jar, covered by a plate of glazed porcelain, through which passed the two pure carbon electrodes and a glass tube bent at right angles. Through this latter a current of perfectly dry hydrogen, devoid of nitrogen, was led above the fused salt. After completely cooling, the contents of the jar were taken up by ice-cold water and then directly washed in alcohol, since uranium in a fine state of division decomposes water at the ordinary temperature. By using an iron electrode, alloys of uranium and iron can be obtained. These are white as silver, can be easily filed, and have a very fine grain.

Uranium, when fairly pure, is absolutely white; when yellow, nitrogen is probably present. Uranium can be filed easily and will not scratch glass. It carbonises slightly when heated in carbon dust, and can be tempered. When free from iron it is non-magnetic. Uranium is much more volatile than iron in the electric furnace, and can be distilled, small metallic spheres, free from carbon, being obtained on condensing the vapour.—A. S.

#### PATENTS.

*Gold, Silver, and other Precious Metals, Electro-depositing, and subsequently Stripping the same from the Cathodes. [Molten Lead Stripping Bath.]* E. Andreoli, London. Eng. Pat. 23,459, Dec. 7, 1895.

THE anodes are formed of peroxidised lead, and the cathodes of iron, or any other convenient metal which will stand the temperature of molten lead or other molten metal or alloy which will absorb the gold. The tank is divided by impervious partitions into compartments in which the electrodes are placed. The electrolyte flows between them in a zig-zag course, and passes out at the upper end. When a sufficient deposit has been obtained on the cathodes they are dipped into a bath of molten lead, covered with a layer of oil, where the gold is removed; and they are then wiped, cleaned, and replaced in the electrolyte.—G. H. R.

*Metal Sheets or Strips by Electro-Deposition, Impts. in or relating to the Manufacture of. [Continuous Deposition.]* K. Klič, Lancaster. Eng. Pat. 26,281, Nov. 20, 1896.

THE deposition is effected on a roller, which may be plain, embossed, or perforated, and which is nearly submerged in the bath in which it revolves. The roller is smeared with a film of tallow, so that the deposit may not adhere, and curved anodes are employed. When the deposit is sufficiently thick, it is cut transversely at the level of the electrolyte, and stripped back sufficiently to admit of its being attached to a band, which passes and re-passes through the electrolyte, over and under rollers, and between upright anodes, which deposit metal on both sides of the strip which forms the cathode. The other end of the band is attached to a reel, on to which the metal sheet is wound, and as it leaves the bath it is cleansed from the solution by a jet of hot water. The process is continuous, as fresh material is deposited on to the roller as fast as the sheet is wound off, and strips of any desired length can be produced.—G. H. R.

## XII.—FATS, OILS, AND SOAP.

*Beeswax and Stearin, Bleaching of.* S. Ramboe. Chem. Zeit. 1896, 20, 1004—1005.

BEESWAX is generally bleached by exposure to sunlight in the form of thin cakes. The process is very slow, and much space is required. A better process is exposure to air artificially enriched with ozone; but although a quicker process than the first, many weeks, or even months, are required. Bleaching by chemical agents is unsatisfactory, as not only the colour, but other qualities of the wax are destroyed by them, and all attempts to restore these qualities have hitherto been unsuccessful.

With the view of shortening, if possible, the natural process of bleaching, the different necessary conditions were studied, with the following results:—As regards the effect of the presence of water, it was found that dry wax takes nearly twice as long to bleach as when 2 to 5 per cent. of water is present. The presence of much moisture in the air, however, retards the bleaching. When wax was kept at a temperature of 0—5° C., direct sunlight had no effect for a long time, whilst at 35° the bleaching was very rapid. Bright daylight, as compared with direct sunlight, has very little effect. It is most important to expose as large a surface of wax as possible. Crude wax, with which half its weight of bleached wax has been mixed, takes only about half the usual time to bleach.

A very quick method of bleaching by sunlight is to prepare an emulsion (by means of the De Laval's emulsor) in water at 60—80° C. This is poured into cold water, to which a little oil of turpentine has been added, when the wax solidifies in minute globules, which, under favourable circumstances, may be bleached in three or four days, when about one-third of previously bleached wax has also been added. When the emulsion apparatus is employed, the wax can be chemically bleached in 10 minutes. Slightly alkaline water (at 80°) is used, and the emulsion treated first with sodium hypochlorite, and, after 10 minutes, with hydrochloric acid until acid. It is then again emulsified to remove the acid. The product is free from ash, and white, but is brittle and odourless.

Bleaching with sunlight, after treatment in the emulsion apparatus, is also recommended for stearine. The bleaching is said to be quick, and the product satisfactory.

—N. H. J. M.

*Oils, The Iodine Absorption of.* H. Mastbaum. Zeits. angew. Chem. 1896, 23, 719—721.

THE author disputes the statement made by Ketel and Amtsch that linseed oil obtained from the seeds by different methods has the same average iodine absorption, no matter how the oil has been extracted. If the seeds are pressed, the expressed oil has a higher iodine value than the oil obtained by extracting the linseed with ordinary solvents. In the latter case the whole of the oil is obtained, whilst in the former the more fluid portion, having a higher iodine absorption, is pressed out. Several results given of experiments with olives bear out this statement, the temperature at which the olives were pressed also having an influence on the iodine value of the oil. It is further well known that this value changes according to the age of the oil. As regards the applicability of the iodine figure for detecting adulteration, its value is lessened, more especially in the case of drying oils, as it is difficult to say whether the deficiency in the amount of iodine absorbed is due to adulteration or to the age of the oil itself.—W. P. S.

*Wool-Fat, The Composition of.* L. Darmstaedter and J. Lifschütz. Ber. 29, 2890—2900.

CONTINUING their researches on the composition of wool-fat (this Journal, 1896, 548), the authors have discovered a new acid in that portion of saponified wool-fat which is soluble in cold alcohol. This acid,  $C_{26}H_{52}O_2$ , lanopalmitic acid, is obtained by first fractionating with calcium chloride, and then partially precipitating the acids obtained, from the insoluble calcium salts with magnesium acetate in alcoholic solution. The portion of magnesium salt insoluble in hot alcohol is filtered off and washed with boiling alcohol. On decomposing the latter, the acid, freed from traces of other acids by means of methyl alcohol, forms a white powder, melting at 87—88° C., and solidifying at 83—85° C. to a lustrous crystalline mass. It has the peculiar property of readily forming an emulsion with water.

When the filtrate from the above magnesium salt is allowed to stand for a few hours, a small quantity of the magnesium salt of carnubic acid separates out. The filtrate from this, when treated with an excess of magnesium acetate, yields corresponding salts of two fatty acids, myristic acid preponderating. In the filtrate from these a further precipitate is obtained consisting of the magnesium salt of an acid of the oleic series.

With the alcohols obtained from wool-fat the authors have made a number of experiments, and have separated them into various groups by the following methods.—30 grms. of the mixed alcohols were dissolved in 1 litre of absolute alcohol, allowed to stand some hours at 15° C., and filtered. The precipitate consists of at least three alcohols, two saturated and one unsaturated. The filtrate gave a saturated alcohol,  $C_{25}H_{50}O$ , carnaubyl alcohol. Again, the filtrate from this, when treated with warm water, yielded a crystalline residue on cooling, which was found to be impure cholesterol. Finally, the solution, after filtering off the cholesterol, was evaporated. A viscous, brown residue remained, which, after removing unsaponified fat, yielded a small quantity of cholesterol.—W. P. S.

*Cotton-Seed Oil, Crude, the Separation and Purification of Colouring Matter from:* Impts. on. E. S. Wilson, Strood, and E. Stewart, London. Eng. Pat. 21,418, Dec. 20, 1895.

THE colouring matter extracted by alkalis or alkaline carbonates (with or without the aid of a soluble sulphite) from crude cotton-seed oil, is purified by fractional precipitation of the solution containing the colouring matter by means of magnesium or calcium chloride or other salts. The fatty acids, resins, and other impurities in the solution are thus separated as insoluble soaps. After removing these soaps, the colouring matter is precipitated with dilute sulphuric or other acid. The flocculent precipitate is filtered off and drained, the resulting product being a paste suitable for use in dyeing, printing, &c.—W. P. S.

*Oleaginous and Fatty Substances of all kinds, and Hydrocarbons; Impts. in the Treatment of.* [Purification.] A. E. Morgans, London. Eng. Pat. 24,714, Dec. 21, 1895.

THE oil to be purified is run into a vessel containing a quantity of warm water. Air is caused to bubble up through the liquids, thereby aerating and washing the oil. The heavier impurities become detached and sink, whilst the air carries off the volatile bodies. The water used, may be pure, or rendered acid, alkaline, saline, or saccharine.

In the treatment of edible fats and oils, butter milk or milk may be used in the place of water.—W. P. S.

*Soap Tablets, Cakes, or Bars with Indelible Colour; Improved Means and Apparatus connected with and for the Marking of.* G. D. MacDougald, Wormit, Fifeshire, and The London and Dundee Syndicate, Ltd., London. Eng. Pat. 3329, Feb. 13, 1896.

THIS process consists of piercing the tablets, bars, or cakes of soap with needles to the required depth, and then placing them in a strong tank fitted with a hermetically closing lid. The tank when so charged is exhausted of air, and liquid colour run in until the soap is covered, whereby the holes in the soap are filled. After drawing off the excess of colouring liquid, the soap is washed with a powerful spray of water.—W. P. S.

*Purifying and Deodorising Butter and other Solid Fats and Oils, Impts. in Processes for.* [Agitation with Cold Water.] J. G. Hargrave and A. Hargrave, Manchester. Eng. Pat. 22,873, Oct. 15, 1896.—W. P. S.

*Varnishes or Compositions, Impts. in Air and Water-proofing.* J. L. Leitch, Paris. Eng. Pat. 2568, Feb. 1, 1896.

THIS is a composition for coating hats and other objects in order to render them waterproof. It consists of: acetone, 300 parts by weight; sulphuric ether and gum lac, of each 50 parts; nitro-cotton, 200 parts; and 100 parts each of acetic ether, camphor, paper (dissolved in sulphuric acid), and mastic.—W. P. S.

*Celluloid [Uninflamable], Impts. in or relating to the Manufacture of.* M. E. Asselot (née Martin), Paris. Eng. Pat. 6389, March 23, 1896.

25 grms. of ordinary celluloid are dissolved in 250 grms. of acetone, and mixed with a solution of 50 grms. of magnesium chloride in 150 grms. of alcohol, until a paste is finally obtained containing, say, 20 grms. of the latter solution to every 100 grms. of the former solution. This paste, after being thoroughly mixed and dried, is the non-inflamable celluloid forming the subject of the invention. The material thus modified, is said to be "absolutely non-inflamable."—R. B. P.

#### (C).—INDIA-RUBBER, &c.

*India-Rubber Industry, The.* R. Robine. *Rev. Chim.* Ind. 1896, 307.

THE best qualities of india-rubber are still those collected in the districts surrounding the River Amazon. But with the rapidly increasing demand, African and Asiatic brands entered the market. *Para rubber* maintains its reputation as the highest quality amongst the different brands. Its loss in washing is from 10 to 16 per cent. *Negrohead* loses from 25 to 35 per cent. *Matto Grosso*, which approaches *Para* in purity, loses only about 10 per cent. in washing. *Pernambuco*, *Maranhão*, and *Bahia* lose from 30 to 40 per cent. *Ceará*, a very good brand, loses about 20 per cent. The losses on purifying the African qualities, are generally considerably higher. The Asiatic brands, which at one time used to be of high quality and very plentiful, have of late years deteriorated in quality and suffered a considerable reduction in quantity owing to the reckless methods adopted for their collection. The purification of the crude india-rubber is effected by first treating it in hot water for from 12 to 24 hours, then cutting it into slices, which are subjected to a repeated passage between friction rollers upon which a supply of water is flowing. The honeycombed sheets thus obtained, are dried in a hot-air stove. The dry sheets are then given solidity and homogeneity by treatment in the masticator or between a horizontal pair of steam-heated friction rollers. Continuous rubber sheets may be obtained by three different methods, and are accordingly described as cut sheets, rolled sheets, and spread sheets respectively. India-rubber tubing is produced by pressing the india-rubber through a nozzle, in the centre of which a fixed core is arranged. The tubes so produced, are laid in flat spirals on cask beds, and are in this state vulcanised. India-rubber threads of square cross-section are manufactured by cutting india-rubber sheets by means of suitable cutting-machines. Threads of circular cross-section are obtained by pressing india-rubber dough through mouth-pieces of the desired cross-section. Moulded articles are manufactured by pressing india-rubber sheets, or dough, into suitable moulds which are heated to the required temperature. India-rubber toy-balls are produced by cutting india-rubber sheets into spherical segments, which are cemented together with india-rubber solution. Before finally closing the body so formed, a small quantity of ammonium carbonate is introduced into it, and the opening closed with a small disc of india-rubber. The

body thus formed is placed in a mould and gently heated, whereupon the dissociating ammonium carbonate distends the ball. India-rubber belting is obtained by coating stout cotton cloth on both sides with india-rubber solution. Several of these fabrics are then united by pressure, and subsequently the whole is covered over with india-rubber sheets. Insulated electric cables are manufactured by india-rubber tape wound round the strands to be insulated. These tapes are held in position by similar strips of cotton cloth lapped on in the opposite direction. The cables are then vulcanised in a closed vulcaniser. The manufacture of pneumatic tyres is carried out by cutting strips of india-rubber sheet of a length corresponding to the circumference of the wheels, but successively decreasing in width. These strips are then, in the order of their widths, cemented one upon the other, so that the central longitudinal axis of the first, forms also the axis of the whole fabric. The whole is then steam-vulcanised. The ends of the band so obtained are then joined together. For the purpose of vulcanisation, from 7 to 15 per cent. of sulphur are generally used, but only from 1 to 2 per cent. combine with the india-rubber. The different vulcanisation processes employed are:—(1.) Vulcanisation in a bath of molten sulphur. (2.) Steam vulcanisation. (3.) Dry-heat vulcanisation. (4.) Cold vulcanisation. (5.) Vapour vulcanisation. The first of these processes is practically obsolete; the second is largely employed for the vulcanisation of india-rubber goods of various descriptions; the third process is extensively used, especially for the vulcanisation of waterproof cloth. The temperature in these processes is 170° C. The fourth of the above processes is chiefly used for the vulcanisation of waterproof cloth, and of thin india-rubber sheets. The process is carried out by treating the articles to be vulcanised with a solution of sulphur monochloride in carbon disulphide or benzene. In the fifth process, the goods to be vulcanised are exposed to the vapour of sulphur monochloride, either by itself or in conjunction with gaseous nitric acid, or nitric, or nitrous oxide.—C. O. W.

#### XIV.—TANNING, LEATHER, GLUE, SIZE.

“*Suède*” or Kid Tanning. *Der Gerber*, 23, 29.

The superiority of French “*Suède*” glove leather, or glove kid finished on the flesh, lies in the expert knowledge the producers possess that the skins from one source are, and that those from another source are not, suitable for their purpose. Of the suitable kinds, American goat-skins and some kinds of African lamb-skins are more particularly noteworthy. The skins should be strong and firm in structure, but without the fibre being thin and rough. Young goat-skins approach very near to the desired conditions, but are mostly too small for the purpose. Sheep-skins are too loose in structure.—C. O. W.

*A Cheap Chrome Tannage.* H. R. Procter. *Leather Trades Circular and Review*, Jan. 12, 1897.

The process of making a basic chrome liquor for tanning, as described in Eng. Pat. 7732, 1893, this *Journal*, 1893, 612, taken out by J. D. Gallagher, on behalf of Martin Dennis, is said to be roundabout and expensive. A simpler and more satisfactory method consists in reducing bichromate of potash at once with a calculated quantity of acid only sufficient to form the required basic salt. Glucose is conveniently employed as a reducing agent, as it becomes completely oxidised to water and CO<sub>2</sub>, but cane sugar, starch, oxalic acid, hyposulphite (thiosulphate) of soda, and other bodies may be substituted. The liquor is made as follows:—3 lb. of bichromate of potash is dissolved in hot water and half a gallon of strong hydrochloric acid (32° Tw.) is added, then glucose gradually, heating, if necessary, till the yellow liquid changes to a deep clear blue-green. Sulphuric acid (2½ lb., 168° Tw.) may be used instead of hydrochloric, but makes a somewhat harder and plumper leather. About 1½ lb. of glucose is required, and the operation should be performed in a good-sized vessel. The solution is made up to 2 galls. For tanning, the goods are placed in a liquor containing, at first, 2 per cent. of this strong solution, but

gradually strengthened to 6 or 8 per cent. Light goods are kept in motion by a paddle, heavier ones are best suspended on a frame, to which a gentle to and fro motion is given. Thick hides can be fully tanned in a week. The process is complete when the hide shows a uniform blue colour throughout. The liquors may be spent by green goods, as in bark tanning: 5–15 per cent. of salt (reckoned on the tanning liquor) will make the leather softer and somewhat looser; whether salt is used or not the leather is tough and stands the boiling test. The fully-tanned leather is well-washed with warm water, and treated with a  $\frac{1}{2}$ – $\frac{3}{4}$  per cent. borax bath as in the two-bath process.—J. T. W.

*Perchlorates in Chili Nitrate of Soda as a cause of Injury to Rye.* B. Sjöllema. *Chem. Zeit.* 1896, 20, 1002–1004.

The injury to rye after the application of commercial nitrate of soda, occasionally observed in Belgium since 1892, is now shown to be due to the presence of perchloric acid, probably in the form of the potassium salt. The effect of the perchlorate is seen some (2–4) weeks after the nitrate containing it is applied. The crop is sometimes quite destroyed and has to be ploughed in; in other cases in which the injury is less, the plants are stunted and the seed small. A number of direct experiments on the effect of perchlorate on germination and on growth were made. The results showed that perchlorate in small quantities retards growth, whilst with 0.5 gm. of potassium perchlorate in 3 kilos. of soil the plants were soon destroyed. The experiments do not, so far, decide what percentage of perchlorate in nitrate of soda is injurious (with an application of 200 kilos. per hectare), but as little as 0.5 per cent. would probably be slightly prejudicial. The samples of Chili nitrate analysed, contained from 0.08 to 6.79 per cent., but 0.94 was the lowest percentage in the samples of nitrate which proved injurious.

The author suggests that the perchlorates found in nitrate of soda may have been formed from chlorides by bacteria, or possibly by chemical action, analogous to the production of iodates and periodates from iodides (Guyard, *Ber.* 1874, 7, 1040).—N. H. J. M.

#### XVI.—SUGAR, STARCH, GUM, Etc.

*Vacuum Apparatus, Temperature of Vapour and Sugar Juice in.* H. Claassen. *Zeits. Zuckerind. Böhm.* 21, 263–265.

The author confirms the facts brought forward by Curin on this subject (this *Journal*, 1897, 55), but does not agree with his explanation of the difference in temperature observed between the vapour and syrup. The vapour escaping from the liquid is not, as Curin supposes, saturated, but as Regnault and Magnus have shown, superheated, and the lower temperature of the vapour is attributed to the unavoidable cooling effect of the walls of the vessel. Bubbles of steam forming on the heating surface have the temperature corresponding to the pressure at that point, including the column of liquid, but only at the moment of formation. Any higher temperature of the liquid is quickly equalised by circulation and a thermometer inserted at any level merely shows this average temperature, and not that of a particular layer.—L. J. de W.

*Aqueous Digestion [Beetroot Pulp].* H. Pellet. Bull. de l'Assoc. des Chim. de Suer. et de Dist. 1896, **14**, 489, 492. This Journal, 1896, 746 and 819.

In reply to the critique of Antusiewicz (*loc. cit.* 1896, 95), Pellet maintains that if the instructions he gave in 1888 and 1889 are followed, with regard to the fineness of the pulp, the concentration, and the quantity of basic lead acetate added, the method of cold aqueous digestion gives results in close agreement with those obtained by the alcoholic method.

—L. J. de W.

*Beetroot Juice, Nitrogenous Constituents of.* E. O. von Lippmann. Ber. 1896, **29**, 2645—2651.

A somewhat limited number of the nitrogenous constituents of beetroots and beetroot juice is to be found described in current literature. Among these may be mentioned asparagine, glutamine, together with their related acids, betaine and choline, also leucine, tyrosine, glutaminic acid, pyroglutaminic acid, citrazinic acid, lecithin, and legumin.

In describing lecithin (Ber. 1887, **20**, 3201) the author incidentally stated that other substances containing phosphorus and closely resembling nuclein might be extracted by alkalis from the tissues of beetroots, after the latter had been exhausted with water, alcohol, and ether. Further, the decomposition products of these substances, namely, the xanthine bodies, ultimately find their way into the molasses.

In prosecuting further investigations on the question, the author submitted to examination certain liquors occurring in de-saccharification processes, instead of molasses. The method adopted was as follows:—After removal of the lime, the liquors were neutralised and repeatedly treated in a somewhat dilute solution with small quantities of basic lead acetate, subsequently they were fractionally precipitated alternately (according to Scheibler's directions) with phosphotungstic acid and mercuric nitrate. The substances were liberated from the precipitates, purified by repeated boiling, washing, and treatment with animal charcoal, and finally purified from phosphotungstic acid and mercuric salts by fractional crystallisation and precipitation.

In addition to those mentioned above, the following substances were identified: xanthine, guanine, hypoxanthine, adenine, carnine, argentine, guanidine, allantoin, vermine, and possibly also vicine. Phosphotungstic acid precipitates the xanthine bodies, also argentine, vermine, and guanidine; but the precipitates are soluble in excess of the precipitant. Mercuric nitrate acts similarly, and also precipitates allantoin, which is not precipitated by mercuric chloride; the latter reagent however, precipitates xanthine bodies and vicine. Ammoniacal silver nitrate, or cuprous chloride solution, is a convenient precipitant for the xanthine bodies (Balke, J. Pr. Chem. [2], **47**, 537); nascent cuprous oxide, that is to say, Fehling's solution together with a reducing sugar, behaves in an analogous manner (Dreesel, Ber. **25**, 2451; Krüger, Zeits. f. Phys. Chem. **18**, 351). The basic mixture is most readily dealt with by means of mercuric chloride; after the filtrate has been freed from mercury and evaporated, xanthine is the first body to crystallise out, then follow guanine, generally mixed with other substances, finally hypoxanthine and adenine. Xanthine is purified by repeatedly dissolving in ammonia and cautiously adding acetic acid, guanine by precipitating a solution in hydrochloric acid with an excess of ammonia. Hypoxanthine is separated from guanine and adenine, either by Schindler's method (Zeit. Phys. Chem. **23**, 432) of the silver compound, or by the pierates (Bruhns, Ber. **14**, 533; Wulff, *ibid.* **17**, 468; Bruhns, *ibid.* **23**, 225). Hypoxanthine remains in solution and can be precipitated by ammoniacal silver nitrate, whereas, to separate guanine and adenine from the recovered pierates, crystallisation of the hydrochlorides as well as the sparing solubility of the former in warm aqueous ammonia, can be taken advantage of (Schindler, *loc. cit.*). Hypoxanthine is separated from the remaining xanthine by treatment with ammoniacal silver nitrate, and by dissolving the precipitate in the least possible quantity of hot concentrated nitric acid; hypoxanthine nitrate crystallises from the solution, whilst xanthine may be obtained from the filtrate by addition of ammoniacal silver nitrate solution. Adenine and hypoxanthine are separated, either by one of the above

given methods or by Krüger's method (*loc. cit.*) by means of copper sulphate and sodium thio-sulphate, which in the cold precipitate adenine only.

The author gives analyses and full descriptions of the various compounds.

According to Rütthausen (Ber. **29**, 894 and 2108) vicine is a glucoside, yielding on hydrolysis a reducing sugar.

—J. L. B.

*Masseccites, A New Method for determining the Density of.* J. Curin. Bull. de l'Assoc. des Chim. de Suer. et de Dist. 1896, **14**, 492—496.

The density of the normal weight made up to 100 c.c. is taken, and the degree Brix corresponding to this density multiplied by the factor:  $\frac{100 \text{ c.c.}}{26.018}$  gives the degree Brix of the original masseccite. The polarisation may be made on the same solution, after weighing, by adding a carefully measured quantity of basic acetate of lead and correcting for the alteration in volume. A table is given ranging from 86.34 to 98.13 per cent. of solids in the masseccites.

—L. J. de W.

*Ammonia in the Manufacture of Beetroot Sugar.* L. Jerser. Bull. de l'Assoc. des Chim. de Suer. et de Dist. 1896, **14**, 529—532. Deutsche Zuckerind., Aug. 7, 1896.

FOLLOWING up the formation of ammonia in the course of the manufacture of beetroot sugar, 100 c.c. of juice were taken from each diffuser and distilled with 1 to 20 c.c. of normal caustic soda. The quantity of ammonia obtained was found to increase from diffuser to diffuser, and with the amount of alkali added, leading to the conclusion that the ammonia is not present as a salt, which would diffuse in the earlier stages of the process, but probably exists combined as a nitrogenous organic substance. After de-fecating at 70° C. for 12 minutes with 2½ per cent. of dry lime, a sample was taken and filtered rapidly, made neutral to phenolphthalein with acetic acid, and tested as before. Although more ammonia was found, the quantity was less influenced by increasing the alkali. The nitrogenous compounds are changed by defecation into compounds more easily decomposed. Saturation juice behaved similarly, the effect of alkali being even less marked. In the further course of manufacture the juice continually loses ammonia, so that the masseccite contains very little. The easily decomposable ammonia disappears, and that decomposed with difficulty remains, without modification, in the syrup. The change in the nitrogenous compounds takes place chiefly during defecation, and at different stations the longer the duration of defecation and the higher the temperature employed, the poorer will the weak juices be in ammonia, and the more will the evaporators be spared.

The disengagement of ammonia is in intimate relation with the loss of alkalinity from the ammonia set free and the alkali neutralised. But it is not possible to determine exactly the loss of alkalinity from the ammonia expelled. The alkalinity of the products of decomposition of glutamine is greater by one equivalent of alkali as indicated both by phenolphthalein and litmus. With asparagine this reaction occurs only with phenolphthalein. Although the decomposition of notable quantities of glutamine is not to be expected during the manufacture, yet the reaction should be taken into account, for an increase of the alkalinity of the juice is actually observable in course of manufacture. From the practical point of view we may conclude, without other considerations, as to the loss of alkalinity, by the loss of ammonia.—L. J. de W.

*Animal Charcoal, The Weinrich Process for the Rectification of.* G. M. Newhall. Bull. de l'Assoc. des Chim. de Suer. et de Dist. 1896, **14**, 537.

THE char from the filter is washed and then dried in an apparatus which utilises the waste heat from the decarboniser to which the heated and partially dried char is next passed. The decarboniser is a revolving cylinder, 4 ft. in diameter and 20 ft. long, heated externally. The char is heated in presence of air to a temperature lower than that in char kilns. After cooling, it is ready to be used afresh.

According to Newhall this process has given good results in the National Sugar Refinery.

The carbon of a char containing usually 12 per cent. was reduced to 9 per cent. It was tested in comparison with the char not revived, the syrup employed showing 200 on the colorimetric scale. After filtration the colours were : from non-revived char, 80, and from revived char, 27.

The composition of the char was as follows :—

	Before Decarbomising.	After.
Carbon .....	12.320	8.900
Carbonate of lime .....	3.320	3.260
Iron .....	0.320	0.210
Sulphate of lime .....	0.904	0.877
Sulphite of lime .....	0.028	0.494

—L. J. de W.

*Fodder, Manufacture of, from Molasses and desiccated Beet Pulp.* L. Wustenhagen. Bull. de l'Assoc. Chim. de Suer. et Dist. 1896, 14, 542—543.

The pulp is sprinkled with 6 to 7 per cent. of molasses slightly warm, and brought directly to the drier by an endless screw or an elevator. By using this proportion a product is obtained which is not sticky. It is readily taken by cattle, and has a higher nutritive value than ordinary dried pulp. (Austrian Pat. 415,235.)—L. J. de W.

*Sulphite of Lime, Solubility of, in Sugar Liquors.* J. Weissberg. Bull. de l'Assoc. des Chim. de Suer. et de Dist. 1896, 14, 485—489.

On sulphiting sugar juice in the works, sulphite of lime is formed, which gradually passes into sulphate of lime at the high temperatures employed, and in the final stages of the manufacture little or no sulphite can be detected. Moreover, certain organic non-sugars of the juice may be reduced, also giving rise to a change of sulphites into the corresponding sulphates. Owing to the rapidity of this change, the difficulty of preparing a sulphite free from sulphate, and the greater solubility of sulphate of lime, it is almost impossible to determine exactly the solubility of sulphite of lime in water and sugar liquors. In Wurtz's dictionary we find : "one part of sulphite [of lime] dissolves in 800 parts of water." According to Battut (Bull. Assoc. Chim. 8, 226—227) a 10 per cent. solution of sugar dissolves 0.036, and a 30 per cent. solution, 0.0374 per cent. of sulphite of lime. These figures being calculated from the lime present, are too high, the greater portion having passed into solution as sulphate. Eckleben (v. Lippmann, Chemie d. Zuck. 648) found that an 8 per cent. solution of sugar dissolved 0.015674 per cent. Weissberg added freshly prepared sulphite of lime in excess (0.5 gram. to 250 c.c.) to water and sugar solutions at 18° C., agitated for some time, and filtered. The sulphurous acid was titrated with iodine, and calculated to sulphite of lime. Water dissolved 0.0043 per cent., 10 per cent. solution of sugar, 0.00825 per cent., and 30 per cent. solution, 0.00800 per cent. of sulphite of lime. After standing for 24 hours, or after boiling for two hours under an inverted condenser, the 10 per cent. solution showed 0.0066 per cent. and 0.0025 per cent. of sulphite of lime respectively.—L. J. de W.

*Starch Formation, Observations on.* T. Bokorny. Chem. Zeit. 1896, 20, 1005—1006.

LAURENT's experiments with etiolated potato sprouts showed abundant deposition of starch in presence of cane sugar or dextrose. The author obtained the same results with potatoes, but with *Spirogyra macina* there was no production of starch from cane-sugar solution, from dextrose, or from xylose. *Spirogyra* even became free from starch when kept dark for some days in 1 per cent. dextrose (with and without addition of calcium nitrate). Under the influence of light *Spirogyra* readily produced starch from cane sugar, grape sugar, and glycerol, &c., provided that oxygen is present. In an atmosphere of hydrogen not a trace of starch was formed.—N. H. J. M.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*Hops, The Sulphuring of.* J. Behrens. Woch. für Bran. 13, 917—923.

THE sulphuring of hops has no influence whatever on their hygroscopicity, sulphured and unsulphured dry hops taking up an equal quantity of moisture from the air under the same conditions. Very exhaustive experiments on the action of sulphuring on the micro-organisms of hops, carried out with various growths of hops, by inoculation into solutions of ammonium succinate and mineral ash, and also into hop extract, and by plate cultures, showed conclusively that its disinfecting power was very imperfect and unreliable, the cultures of sulphured hops showing bacterial and mould growth in every experiment, even though the exposure to sulphur dioxide, and the amount of this gas absorbed by the hops, considerably exceeded what would obtain in commercial practice. A plate-culture determination of the total number of micro-organisms existing on a sample of hops before and after very excessive sulphuring, gave the following result :—Unsulphured : Total organisms per gram. of hops, 13,637,600, including 422,800 mould spores. Sulphured : 8,056,300 organisms, including 169,200 moulds. The only one of the results attributed to the action of sulphur which has any foundation, is the improvement in colour, which is a doubtful advantage, as only brown and second-rate hops would be affected by it.

Hops absorb sulphurous acid, and the more the longer they are exposed to it. Only a part of the absorbed gas remains unaltered, another part is oxidised to sulphuric acid, and a third enters into combination with alkaline organic compounds existent in the hops.

Endeavours were made to find a substitute for sulphurous acid. Exposure to formalin did not effect disinfection, but treatment with chloroform vapour completely sterilised the hops, when applied in sufficient quantity. It produced at the same time a depreciation in colour, but did not appear to exert any prejudicial effect on the fermentation of the wort which was hopped with the hops so treated.—J. G. W.

*The Action of Diastase on Starch.* A. R. Ling and J. L. Baker. Proc. Chem. Soc. 1897, [173], 3—4.

THE authors show that maltose, when heated with Fehling's solution, under the conditions prescribed by Wein, reduces 1.079 grms. of copper per gram. of sugar. The table of Wein, therefore, gives results which are 4.5 per cent. too low, a result also arrived at by Brown, Morris, and Millar.

They have examined in detail the products of the limited action of diastase on starch at 70°, and have separated maltose and the following unfermentable substances, which were purified to such an extent as to free them from all extraneous matter.

*Maltodextrin α*,  $C_{36}H_{62}O_{31}$ , identical with Brown and Morris's maltodextrin, but having the properties  $[\alpha]_D = 180$ ,  $R = 32.81$ .

*Maltodextrin β*,  $C_{21}H_{42}O_{21}$ , identical with Prior's "achroodextrin III," and having the properties  $[\alpha]_D = 171.6$  and  $R = 43$ .

A substance,  $C_{12}H_{20}O_{11}$ , isomeric with maltose, and obtained from the unfermentable residue of that particular fraction previously called isomaltose by Lintner. It had the constants  $[\alpha]_D = 156$  and  $R = 62.5$ , and may consist of the simple "dextrin,"  $C_{12}H_{20}O_{10} + H_2O$ , the existence

of which, the authors' previous work foreshadowed. Inasmuch as it gave a small amount of crystalline osazone, it perhaps contained maltose.

When the three substances above named are treated with an excess of diastase at 60° for a few hours, the approximate reducing powers of the products are R = 90, 91.5, 91 respectively.

There are now ample data by which to conclude that starch, when hydrolysed by diastase, is converted into a series of maltodextrins of gradually decreasing molecular weight and optical rotatory power, and of increasing reducing power. These appear to have the optical and reducing properties of mixtures of the original starch and maltose.

*Beetroot Juice, Difficulties in the Fermentation of.* G. Arachequesne. Bull. de l'Assoc. des Chim. de Sucr. et de Dist. 1896, 14, 508—516.

JUICE from beetroots gathered during the rainy period following the long drought of 1895 refused to ferment. Hydrofluoric acid and formalin produced no improvement, but it appeared that the cause might be the antiseptic action of volatile acids, as acetic or formic acids, or of a fixed acid as oxalic acid, liberated by sulphuric acid. Barbet suggested the existence of a special diastase in unripe beetroots having a saccharogenic action, the effect of which counterbalanced the saccharophagic action of the sucrase or invertin of the yeast.

It was found that juice boiled for a few minutes, after acidifying, fermented normally, as did also juice obtained from the same beets after being stored in silos. The addition of lime to remove oxalic acid had to be abandoned on account of the butyric fermentation which followed the reduction of the acidity.—L. J. de W.

*Dextrose, Levulose, and Invert Sugar, The Solution Density and Cupric-Reducing Power of.* H. T. Brown, G. H. Morris, and J. H. Millar. Proc. Chem. Soc. 1897, [173], 4—5.

See under XXIII., page 166.

*Antiseptics, Use of, in Spirit Production and in Yeast Production.* F. Rothenbach. Zeits. f. Spiritusind. 1896, 19, 361.

THE author draws the following conclusions from his experiments:—

1. Formaldehyde and hydrofluoric acid appear to be the only specific antiseptics against bacteria (spalt-pilze), but other substances are nevertheless more or less suitable for use.

2. The best results were obtained when hydrochloric acid was used during the growth of the yeast.

3. The morphological and physiological characteristics of the yeast species are modified in different ways by the different antiseptics.

4. With careful choice of conditions, a long acclimating of the yeast to the antiseptic is not necessary, a few cultures generally giving satisfactory results.

5. When fairly good potatoes are used, the most harmful bacteria generally come from the stock-yeast rather than from the green malt. This stock-yeast should then either be changed or be purified by means of formalin.

6. In practice, the best yield of alcohol is obtained with yeast which is free from bacteria.

7. Of the prophylactic or purifying media, formalin is preferable, as hydrofluoric acid is more weakening to the yeast cells.

8. The high yield of alcohol obtained where formalin is employed is probably due to the smallness of the quantity of acid present, and the consequently stronger and more continuous saccharification of the mash.

9. In practice, yeast prepared with hydrochloric acid and formalin should yield at least as good results as the lactic acid yeast, especially in distilleries where high acid production occurs.

10. Whether the hydrochloric or the lactic acid method is being employed, the use of formalin is advisable to keep down the development of bacteria. This addition may be made to the yeast, and in the fermenting vessels.

—L. T. T.

*Dried Yeast, Duration of Life of.* H. Will. Zeits. ges. Brauw. 1896, 19, 453.

THE author finds that in some cases the duration of life of dried yeast is very great, in some of his experiments even exceeding nine years. As a rule, the wild yeasts are stronger in this respect than the ordinary cultivated forms. *Saccharomyces apiculatus* and the allied species appear especially durable. The best results are obtained when the yeast is mixed with an indifferent substance which is neither hygroscopic nor dehydrating in properties, and rapidly dried at a temperature which is slowly raised to, but does not exceed, 40° C. The best material to use is sawdust and next charcoal. Gypsum or infusorial earth does not give such good results.—L. T. T.

*On the Influence of Strong Light on the Cell Formation of Saccharomyces Cerevisiae.* W. Lohmann. Wochenschr. für Brauerei, 1896, 1342.

THE author has investigated the effect of a strong electric light and of sunlight on a single yeast cell growing in wort gelatin, and kept under constant conditions of heat and moisture on a microscopic slide.

It was found that, if the temperature be not too low, both lights hindered the budding of the cell, and appeared to injure it if the exposure to the light was prolonged. If the temperature was low the effect was not so marked.

The effect of strong light on *Mycoderma Cerevisiae*, *Torula*, and on *Saccharomyces Pastorianus* L., was also determined, and the latter was found to have a much greater power of resistance to the light than the others.

—A. L. S.

*Diastase, Chemical Nature of.* T. B. Osborne and G. F. Campbell. J. Amer. Chem. Soc. 1896, 18, 536—542.

IN a previous paper, Osborne (this Journal, 1896, 44) described some attempts to isolate diastase. In the present communication the former results are confirmed, although no more highly active diastase than that before described, has been prepared. The authors now separate the diastase by treating the finely ground malt with 5 per cent. sodium chloride solution, and saturating the filtered extract with ammonium sulphate. The precipitate was dissolved in brine, and the filtered solution saturated with ammonium sulphate, the subsequent method of treatment being practically the same as that previously described *loc. cit.* The result of this experiment shows that little diastase was precipitated by bringing the alcohol content of the malt extract to 50 per cent. by weight, whilst nearly all the diastase was thrown down when the proportion of alcohol in the malt extract was made 60 per cent. Experiments were made to isolate diastase from the malt extract of commerce, which had been concentrated at a low temperature *in vacuo*. The authors, however, failed to obtain a product with a higher diastatic capacity than 300.

Several experiments were then made with the object of determining the influence of conditions, such as the age of the diastase solution, the presence of certain substances—especially sodium chloride, disodium hydrogen phosphate, tri-potassium phosphate, orthophosphoric acid, acetic acid, and citric acid. In some cases the results were definite; thus, citric acid in the minutest quantities was always found to depress or destroy diastatic action; but in the majority of the above substances no uniform results were obtainable from which reliable conclusions could be drawn in regard to the circumstances that ensure a high degree of diastatic capacity.

From their experience in testing various preparations, the authors state that the purer the diastase the more sensitive is it to external conditions, and that the method of testing the purity of the ferment by its maltose-producing power becomes of uncertain value, and perhaps fails to furnish a safe criterion of the purity of the enzyme. That the proteid is not the only factor involved in the amylolytic action of diastase is indicated by the great influence on its activity that often accompanies the addition of various substances to its solution. It is therefore not improbable that in attempting to purify diastase, some substance which favours or is essential to its action is removed, and that the enzyme itself is being dealt with,

which is feeble in its action through the absence or deficiency of some accessory substance. Thus the addition of sodium chloride in many cases increases the diastatic action. Experience tends to show that albumin is an essential factor in diastatic action. In all the preparations made, none from which albumin was absent showed amylolytic power, and those containing the most albumin were the most active. It was always possible to roughly judge of the diastatic power of a preparation by heating a portion of its solution to 65° C. and observing the amount of coagulum formed.

The fact that active diastase was only obtained from solutions, the alcohol content of which was between 50 and 60 per cent., may be regarded as fair evidence that the enzyme is not carried down mechanically with the proteid.

—J. L. B.

*Wine from Wine-Press Residues.* Spaeth and Thiel. Zeits. angew. Chem. 1896, 23, 721—727.

AFTER pressing grapes and obtaining a juice which yields a good wine, the residue of the fruit is further treated, in order to procure a secondary fluid which, when fermented, gives a wine of poorer quality. The methods used for this purpose are, the addition of sugar and water to the residues, the addition of very dilute alcohol, or allowing the skins, &c. to ferment. After either treatment the juice is expressed. The poor wine thus obtained is sometimes used for adulterating other wines, and the authors give the results of analyses made by themselves of wines, both good and poor, to see whether this adulteration can be detected. They arrived at the conclusion that the small percentage of phosphoric acid in the above wine is the most important factor for detecting its presence. A high percentage of tannin also points to the presence of wine obtained by the before-mentioned processes, although the fining of the wine with white of egg or gelatin tends to reduce the amount of this constituent. Some white wines, however, contain an abnormal quantity of tannin.—W. P. S.

*Wines, Algerian; Lactic Acid contained in.* J. A. Muller. Bull. Soc. Chim. 1896, 15, [23], 1210—1213.

The author gives full analyses of 14 samples of red wines from different districts of Algeria. The chief point to which he draws attention is the abnormal quantity of lactic acid in some of these wines. In seven of the samples, the lactic acid exceeded 2 grms. per litre, and four of these contained from 3.5 to 4.5 grms. According to Gayon and Dubourg, glucose and levulose, under the influence of a special ferment, are broken up into mannite and lactic acid, the proportions of the two former being as 72.0 to 10.1. In the wines analysed by the author, the ratio of lactic acid to mannite is, however, in nearly every case far in excess of the above, and cannot therefore result from a mannitic fermentation of grape sugar. Although the samples rich in lactic acid appeared to contain the characteristic disease filaments described by Pasteur, they cannot be properly regarded as "tournees," as they contained the normal proportions of tartar and glycerin. It is, however, probable that, before attacking the glycerin and the tartar, the ferment decomposes some of the grape sugar still present, with production of lactic acid.—A. K. M.

*Wines, Loss of Colour in ("Casse").* Laborde. Comptes rend. 1896, 123, [24], 1074—1075.

THE loss of colour constituting the disease known as "la casse," is due to a fungus, *Botrytis cinerea*, which, being one of the family of oxidising diastases, appears to exert an oxidising action on the colouring matter when in contact with air. This fungus can be destroyed by heat, a temperature of 70° C. being sufficient to destroy the oxidising diastatic growth in the wine. This temperature, however, is a much lower one than would suffice for the destruction of the organism in cultures of the same.

—J. T. D.

*Colouring of Wines: possibility of mistaking Coal-tar Colours for Caramel.* A. J. da Cruz Magalhães. Comptes rend. 123, [21], 896—897.

CARAMEL is frequently employed to give a fictitious appearance of age to white wines. The author finds that

certain colour reactions relied upon for the identification of caramel are also afforded by coal-tar colours. Attention is also drawn to the fact that the reactions given by caramel prepared from saccharose are not identical with those of caramel prepared from dextrose.—V. C.

*Alcohol, Denaturing.* G. Arachequesne. Bull. de l'Assoc. des Chim. de Suer. et de Dist. 1896, 14, 516—524.

A MAJORITY of the members of a Commission appointed to study questions relating to denatured alcohol and denaturing agents, are of the opinion that the process of denaturing at present in force in France, based on the employment of methyl alcohol containing acetone, affords the greatest security to the Treasury. The author contends that the method is too costly, and that the alcohol can be purified, and at a considerable profit. He also points out that as denaturing is forbidden in the distilleries, a middleman is necessary, and the chances of fraud are increased.

To illustrate the processes of purification, he gives the following as the composition of a denatured alcohol, worth 46.86 francs per 115 litres:—100 litres of 90° alcohol, 15 litres of crude methyl alcohol ("methylene"), 1 grm. of malachite green, and 500 grms. of petroleum spirit ("heavy benzine"). This mixture would have the following proximate composition:—

	Litres.	Boiling Point.
Anhydrous ethyl alcohol	90.00	° C. 78
" methyl	9.00	66
Water { 10 per cent. of 100 litres	10.00	100
" 15 "	1.50	
Acetone, 25 per cent. of 15 "	3.75	56.4
Pyroligneous impurities, 5 per cent. of 15 litres	0.75	80 to 95
Petroleum spirit, 500 grms.	..	80 to 100
Malachite green, 1 grm.	..	..

The acetone and methyl alcohol might be separated almost completely by a single rectification, and the colour also, but the process would fail in the presence of the pyroligneous impurities and the petroleum spirit. On adding, however, a little chloroform and a suitable salt solution, so as to reduce the alcoholic strength to 10°, and agitating, the liquid separates into three layers: below, the chloroform and methylic impurities; next, the saline layer of weak alcohol; and at the top an oily layer of spirit. These are separated by decantation and the alcohol recovered by distillation. It contained only 0.5 per cent. of methyl alcohol, and not a trace of acetone. The value of the products from 115 litres is estimated at 296.05 francs, and deducting 90 francs, the present cost of the alcohol, leaves a profit of 206 francs. To the objection that chloroform is costly, he replies that it may be produced by the action of chloride of lime and lime on acetone, taking care to keep the solution cool and dilute. It will thus be possible to destroy every trace of acetone without attacking the ethyl alcohol, which is acted on only at a high temperature.

The problem of purifying alcohol becomes more and more difficult in proportion as aldehyde and fusel oil are present from the napeous first and last runnings, especially the latter; and it is a grave mistake to have forbidden more than 1 per cent. of essential oils in alcohols for denaturing. The author suggests that all alcohols in the works regarded as unfit for consumption should be denatured when the manufacturer declares they cannot be improved by further rectifications, chemical or physical.

—L. J. de W.

*Alcoholic Fermentation without Yeast Cells.* E. Buchner. Ber. 30, 117—124. (Preliminary Communication.)

ONE thousand grms. of purified pressed yeast is mixed with an equal weight of quartz sand, and 250 grms. of kieselsol, and well rubbed together until the mass is moist and plastic. The paste is then well mixed with 100 grms. of water, placed in a filter cloth, and subjected to from 40 to 500 atmospheres pressure. About 500 c.c. of extract are obtained.

The pressed cake is again mixed with 100 grms. of water and again pressed, and about 150 c.c. more of extract are obtained. About 500 c.c. of extract can be obtained from 1,000 grms. of yeast, which contain about 300 c.c. of cell-contents. In order to remove a slight turbidity it is shaken up with about 4 grms. of kieselguhr, and filtered through filter paper.

The extract thus obtained forms a clear but opalescent yellow solution, smelling of yeast. Its specific gravity was in one case found to be 1.0416. On boiling, a copious coagulation takes place, and the whole becomes solid. The coagulation begins at 35–40°, and is preceded by an evolution of carbon dioxide, with which the solution is saturated. This solution contained over 10 per cent. of dry substance. In a previously prepared solution there was 6.7 per cent. of dry substance, 1.15 per cent. of ash, 3.7 per cent. of albuminoid.

The remarkable property of this yeast extract is that it is capable of causing alcoholic fermentation of sugar solutions. This was found to take place with solutions of cane sugar, dextrose, levulose, and maltose; but not with mannitol or lactose solutions, these two latter not being fermentable by beer yeast.

Mixtures of the active extract and sugar kept in an ice cupboard for several days became turbid, but no yeast cells could be detected by microscopical examination, and the turbidity appeared to be due to flocks of albumin. If

the mixture be saturated with chloroform the fermentation still goes on, although this appears to cause an earlier slight precipitation of albuminoid. Neither does filtration through a sterilised Berkfeldt kieselguhr filter destroy the fermenting power.

A parchment paper dialyser full of the yeast extract was hung in a 37 per cent. solution of cane sugar; after some hours the surface of the paper was covered with numerous small bubbles of gas, and also there was a lively evolution of gas in the interior, caused by the sugar solution diffusing in.

The activity of the yeast extract does not last long; it had vanished after being kept five days in an ice cupboard, but lasted for two weeks when mixed with cane-sugar solution.

Heated to 40°–50° the extract soon loses its fermenting power. If the extract be precipitated by strong alcohol and the precipitate dried over sulphuric acid, it is found to have lost its fermenting power.

The author proposes the name *Zymase* for this ferment.

—A. L. S.

*Brandy, Composition of.* X. Roques. J. Pharm. Chim. 1897, 5, 55.

The author having analysed a number of samples of Charente brandy which he believes may be considered pure, has tabulated the results as follows:—

	Cognac Types.					Cognac Types.				
	1893.	1892.	1888.	1883.	1873.	1893.	1892.	1888.	1883.	1873.

Higher alcohols	124.72	143.23	123.72	165.31	140.42	186.94
Total (per hectolitre of 100° alcohol), or impurity coefficient.	332.57	304.79	296.25	347.80	471.35	633.86
Total of ethers + higher alcohols	284.85	230.49	245.11	295.86	294.92	377.30
Ratio Higher alcohols	0.8	1.2	1.0	1.3	0.9	1.0
Ethers	0.8	1.2	1.0	1.3	0.9	1.0
Coefficient of oxidation	10.7	14.2	16.3	14.1	37.5	40.2

The following observations are made:—

1. There is considerable difference between the maximum and minimum impurity coefficients; this difference is less if the sum of higher alcohols and ethers be taken, as recommended by Lussou, the proportion of acid being very variable.

2. This total of the higher alcohols and ethers is one of the least variable values as a basis of comparison for brandies; the number, however, increases considerably with the age of the sample. In ageing there is produced a concentration of these two impurities.

3. The ratio  $\frac{\text{Higher alcohols}}{\text{Ethers}}$  is in most cases nearly unity but increases with age.

4. The coefficient of oxidation, i.e., the ratio of aldehydes + acids to total impurities, furnishes to some extent a measure of the age of a brandy, but the coefficient varies very considerably in brandies of the same age but of different sources. The last portions of the distillate being very acid, the acid content will be small or large according to the extent to which distillation is continued in the manufacture.

5. The numbers which express the total coefficient of impurities and the sum of higher alcohols + alcohols give the greatest information as to the nature of a brandy. The former is about 400 and the latter 300.—A. C. W.

## XVIII.—FOODS; SANITATION, WATER PURIFICATION, & DISINFECTANTS.

### (A.)—FOODS.

*Coal-Tar Dyestuffs [for Colouring Edible Substances, &c.] ; The Behaviour of, towards the Process of Digestion.* H. A. Weber. *J. Amer. Chem. Soc.* 1896, 18, 1092–1096.

The effect on digestive ferments was studied of four coal-tar colouring matters known to be employed for the purpose of colouring confectionery, *viz.*, Oroline Yellow ("Fast Yellow"), Saffoline (Acridine Red), Magenta, and Methyl Orange. The experiments were made with pepsin and pancreatin, blood fibrin being digested with the ferment and hydrochloric acid, and parallel tests made with and without addition of the colouring matter. It was found that Acridine Red, Magenta, and Methyl Orange do not interfere with the action of pepsin, but considerably retard that of the pancreatic ferment, whilst in the case of Fast Yellow the exact reverse takes place. Since all these retard the action of one or other of the digestive ferments, they are evidently unsuited for the purpose of colouring articles of food and drink.—R. B. B.

*Albumins, Putrefaction of.* O. Emmerling. *Ber.* 29, 2721.

See under VI., page 140.

### (B.)—SANITATION; WATER PURIFICATION.

*Arsenical Wallpapers, Cause of the Poisonous Action of.* O. Emmerling. *Ber.* 29, 2728.

The author tests the accuracy of the statement that arsenic hydride is evolved by the action of micro-organisms on arsenical wallpapers.

Bonillon cultures of bacillus prodigiosus, violaceus, subtilis, anthracis, fluorescens liquefaciens, proteus vulgaris, several sarcine, and micrococci, were treated with 0.5 per cent. of arsenious acid and a slow current of air passed through the flask and then through several tubes containing silver nitrate solution. No arsine could be found. Moulds were next tried (*Penicillium glaucum*, *mucor mucedo*, and *corymbifer*, *Aspergillus glaucus* and *fumigatus*). These grew on bread paste containing 0.2 per cent. of arsenious acid, and again not a trace of arsine was detected.

Ordinary yeast also ferments arsenical grape sugar solution, without producing arsenic hydride.

The experiments were varied by exposing strips of filter-paper painted with a mixture of starch paste and Schweinfurt green to the air. Numerous colonies of micro-organisms of

all kinds developed, but no arsine was detected. It appears thus that the poisonous effects of arsenical wallpapers must be ascribed to dust.—T. E.

*Waterpipes, Galvanised Wrought Iron [Uninjurious].* Illustr. *Zeit. für Beechind.* 25, [48], 1568.

ACCORDING to reports from a number of American water companies, the objections raised on sanitary grounds against the use of galvanised wrought-iron pipes have no foundation; and the researches of Ruoff have shown that the amount of zinc dissolved by water during an exposure of 8 months is so minute (0.0024 gram. per litre) that it may be regarded as not injurious to health.—C. S.

## PATENTS.

*Purification, Softening, or Hardening of Water for Domestic, Manufacturing, or other Purposes; Apparatus and Process for the.* J. H. Williams, Waterford. *Eng. Pat.* 821, Jan. 13, 1896.

The apparatus comprises a series of tanks or compartments (generally three) arranged at different levels, the water being delivered from each tank to the next lower of the series through a floating hinged tube adapted to retain the sediment, and the lowest tank being provided with a filter, aerating pipe, and suitable inlet and outlet taps and stop cocks where required. In the uppermost or "depositing" tank the water is treated with calcium carbonate, calcium sulphate, alum, potassium or calcium permanganate, or other suitable precipitant; or it may be subjected to the action of an electric current, or a stream of oxygen, in any or all of the tanks. In the intermediate or "neutralising" tank, the water is further treated with softening or precipitating agents, such as borax, sodium or potassium carbonate, &c. In the lowest or "storage" tank, the water is (when necessary) aerated and filtered.—R. A.

*Sewage Precipitation Tanks, Impts. in.* H. Walker, Nottingham. *Eng. Pat.* 9602, May 6, 1896.

THE tank is formed with a sloping bottom, on to which the sewage is delivered through a suitable inlet pipe. The precipitated matter or sludge gradually slides down the sloping bottom, and collects at the deeper side of the tank. The sludge is discharged through a vertical pipe having a horizontal branch outlet, the outlet being fitted to the vertical pipe below the level of the sewage in the tank. The discharge pipes are formed with suitable plug-closed apertures, through which a rod can be inserted for cleaning or clearing purposes. The overflow channel is constructed round the top of the tank.—R. A.

## XIX.—PAPER, PASTEBOARD, Etc.

*Kaolin, Calcium Carbonate in. [Injurious Effects, and Remedy.]* *Papier-Zeit.* 1896, 21, 3138.

DIFFICULTY in sizing some papers has been traced to the kaolin, used for weighting, containing calcium carbonate. Experiments carried out in consequence, showed that when the calcium carbonate in the kaolin exceeded 0.3 per cent., more or less difficulty in the sizing ensued. Of course, the actual limit depended considerably on the kind and thickness of paper and the amount of kaolin used for weighting, &c. The difficulty can be overcome by increasing the quantity of size or by converting the carbonate in the kaolin into sulphate. Where circumstances render the rejection of kaolin found to contain calcium carbonate inconvenient, it is advisable

to convert the carbonate into sulphate. This is best effected by adding to the pulp of kaolin in the vats sulphuric acid of 66° B., to the extent of 1.1 per cent. of the weight of the kaolin for every 1.0 per cent. of calcium carbonate found to be present in the kaolin. The reaction takes place rapidly, the addition of the acid causing increase of temperature of the liquid, and so facilitating the escape of the carbonic anhydride liberated. The mixture should be left for about 10 minutes for the carbonic anhydride to escape, as otherwise the evolution of the bubbles of this gas in the pulp vessels causes inconvenience. As 100 parts of calcium carbonate form 172 parts of gypsum (already sometimes used for weighting under the name of "amaline"), the weight of the kaolin is increased by the treatment, and it may sometimes be found cheaper to treat a local low-priced kaolin containing calcium carbonate than reject it in favour of a higher-priced kaolin from a distance.

—L. T. T.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Eu-Quinine.* C. v. Noorden. Separatabl. aus Centralbl. inn. Med. 1896, No. 48; Chem. Zeit. 20, [104], 315.

ZIMMER and Co., of Frankfurt, have produced a derivative of quinine which, it is alleged, has the characteristic medicinal properties of quinine itself, whilst entirely lacking the bitter taste, &c. characteristic of the drug. It is, moreover, said to possess certain other properties peculiar to quinine, only in a less degree. The new substance, which is termed euquinine, is the ethyl carbonic acid ester of quinine, and has the formula  $\text{C}_6(\text{OC}_2\text{H}_5)(\text{OC}_{20}\text{H}_{23}\text{N}_2\text{O})$ . It is produced by the action of ethyl chlorocarbonate on quinine. It forms delicate white needles, melting at 95° C., slightly soluble in water, but dissolving readily in alcohol, ether, and chloroform. The solution shows a basic reaction with litmus paper, and forms, with acids, salts which crystallise well. The solution in sulphuric or nitric acid exhibits a strong blue fluorescence, as quinine does. Precipitates are formed with the usual alkaloid reagents; and it gives the characteristic green colour with ammonia after the addition of chlorine water, but not the Herapathite reaction. Of the salts, the hydrochloride is easily soluble in water, the sulphate with difficulty, and the tannate with very great difficulty.—W. G. M.

*Codeine and Morphine.* A Solvent [Anisol] which permits of the Separation of. L. Fouquet. J. Pharm. Chim. 1897, 5, 49.

MORPHINE was found by Hugouenq to be soluble in hot anisol, but insoluble in cold; codeine dissolves in the cold liquid. The following are the quantities of the two alkaloids dissolved by 100 parts of this solvent by weight:—

Temperature.	Morphine.	Codeine.
° C.		
9	Insoluble.	7.80
16	..	15.28
100	0.95	161.00
250	4.80	..

The anisol used was very pure. It boiled at 152° C., and had a sp. gr. of 0.991. Morphine may be separated from codeine by trituration with anisol at 15° C. The solubility of codeine in anisol is increased after crystallisation from that solvent.—A. C. W.

*Essential Oils.* Duyk. J. Pharm. Chim. 1896, 4, 491.

A CONTINUATION of articles abstracted in this Journal, 1896, 739 and 919.

*Bergamot Oil.*—This essence, obtained by expression from the peel of the fruit of *citrus bergamia*, is usually more or less green in colour; its density is 0.833 at 15° C., its specific rotation  $\alpha_D = +9^\circ$  to  $+12.5^\circ$  at 15° C.; it is soluble in twice its volume of 80 per cent. alcohol. Oils of orange and lemon are easily detected by the polarimeter after decolorisation

with animal charcoal, oils of lemon and turpentine by their reaction with magenta decolorised by sulphurous acid (see below). The best method for the detection of adulteration is the determination of linalyl esters, of which the oil contains 25—40 per cent. The oil also contains free linalol, limonene, dipentene, a camphor (bergaptene), and compounds of the coumaric series. (Compare Schimmel and Co.; this Journal, 1896, 925.)

*Essence of Néroli* is obtained by the steam distillation of the flowers of *citrus bigaradia*, 1 kilo. of which affords 0.5 to 1 gram. of the oil. This essence is almost entirely composed of limonene and its isomers; these hold in solution the steoptene auradine, to which the odour is in great part due. *Néroline* is the methyl ester of  $\beta$ -naphthol; in alcoholic solution it has the perfume of essence of néroli. The essence is often mixed with essence of petit grain, orange, bergamot, &c. The pure oil has the density 0.881—0.887 at 15° C.; mixed with an equal volume of alcohol a violet fluorescence is to be observed at the surface of the liquid. Essences of néroli, orange, cedrat, bergamot, and petit grain give no coloration with magenta decolorised by sulphurous acid; essence of lemon affords a strong bluish-violet and essence of turpentine a rose coloration. To detect adulterations of the former oils by the latter, triturate a few drops with pure calcium phosphate, treat with distilled water, and filter in a tube; if no coloration be given by the magenta reagent, the oil contains no essence of turpentine or lemon. It is necessary in these experiments to well cork the tube to exclude oxidising action of the air.

To detect essence of petit grain in néroli, add carbon bisulphide in small quantities; the pure oil becomes turbid in contact with the solvent and then gives a clear solution as the quantity of solvent increases. On the contrary, essence of petit grain gives a clear solution with a small quantity, but with a large quantity of carbon bisulphide an opaque whitish liquid.

*Essence of Cajuput* is contained in all parts of *melaleuca*, a tree growing in Indian countries. It has a camphor-like odour, a burning taste, and the density 0.889—0.918 at 15° C. It contains cineol,  $\text{C}_{10}\text{H}_{18}\text{O}$ , a hydrocarbon not yet studied, and traces of esters. To obtain cineol (eucalyptol) from essence of cajuput or eucalyptus, treat with a very concentrated solution of phosphoric acid, subject the compact mass to strong pressure, wash with ether, add warm water, decant, wash, and dry the supernatant cineol.

*Eucalyptus Oil.*—The essential oil of *E. globulus* is the most highly prized. This species, growing especially in Algeria, contains 1—3 per cent. of the oil, which consists essentially of cineol (50 to 70 per cent.), and contains also dipentene and a pinene of boiling point 158°, which forms a crystalline dextro-rotatory hydrochloride. The essential oil of the Australian variety, *E. amygdalina*, contains little cineol but much eucalyptene,  $\text{C}_{10}\text{H}_{16}$ , which does not form a solid hydrochloride. To distinguish the two essences, wet the surface of a tube with the oil and expose to the action of bromine vapour; the essential oil of *E. globulus* produces crystals, but other essential oils give nothing similar. Essences of eucalyptus and cajuput have a varying action on polarised light; eucalyptol, which is sometimes substituted for them, is inactive. Cineol and the essential oils in which it is found give a violent reaction with iodine; this property permits of the detection of turpentine.

*Mint Oils.*—There are many varieties known in commerce, derived from the following plants:—*M. piperita* (peppermint), *M. arvensis piperascens* (Japanese mint), *M. viridis*, *M. crispata*, *M. pulegium*. In general they are characterised by the presence of menthol in the free state, and as esters of acetic, butyric, and isovaleric acids. In addition, the ketone menthone, the hydrocarbons menthene, pinene, phellandrene, cadinene, acids, &c., are found.

The English (Mitcham) peppermint oil is the most esteemed and the most often adulterated. The density varies from 0.840 to 0.975; it is completely soluble in rectified spirit, incompletely in carbon bisulphide; 70 per cent. alcohol dissolves one-fifth of its volume of essence of best quality, and leaves almost undissolved the American oil or essence of turpentine. Glacial acetic acid enables a recent essence to be distinguished: five drops of essence of

peppermint and 1 c.c. of acid give a green coloration, which appears red by reflected light; old essences do not produce this phenomenon.

The Zeiss butyrorefractometer gives valuable indications as to the purity of peppermint oils. In daylight the Mitcham essence gives a narrow band hardly coloured blue at the edges, occupying the divisions 50—53; the essential oils of *M. crispata* and *pulegium*, on the contrary, give broad bands in which blue and violet predominate. With sodium light the following indices were found:—

Mitcham oil .....	52
" (old) .....	57
French I. ....	57.58
Saxon .....	51
Japanese (menthol extracted) .....	75.5
French II. ....	53
" III. ....	52.25
American .....	50.7
" (old) .....	62
<i>M. crispata</i> .....	94.5
<i>M. pulegium</i> .....	88.5

There is good reason to suspect any essence the index of which on this scale does not fall between 50° and 60° at 25° C., and the line of demarcation of which is not sharp.

Mint oils are levo-rotatory, for English oil  $\alpha_D^{20} = -34^\circ 29'$ ; French,  $-14^\circ 3'$ ; Japanese,  $-105^\circ$  to  $-106^\circ$ ; they begin to boil at  $203^\circ$ — $209^\circ$  under ordinary pressure. Deflagration is produced by the addition of powdered iodine; if this is not the case, the presence of essence of *M. crispata*, or oil of turpentine, is to be suspected.

Strongly cooled, the stearoptene menthol is separated. In the Mitcham oil this reaches 53 per cent., in the Japanese 72 per cent.; the greater part of the stearoptene is usually extracted from the latter oil. In a suspected oil the menthol should be determined: first saponify the esters by boiling with normal alcoholic soda solution; titrate the excess of alkali. Boil with acetic anhydride and determine the esters formed as before. Treat the oily residue with sodium. Menthone is reduced to menthol, and can then be determined. Essence of camphor is detected by the polarimeter, its rotatory power +  $34^\circ$  being opposite in direction to that of oil of peppermint.—A. C. W.

#### Essential Oil of Buchu Leaves, Composition of. Kondakoff. J. Prakt. Chem. 1896, 54, 433.

The stearoptene of this oil, diosphenol,  $C_{10}H_{16}O_2$ , has been shown by Flückiger and Shinoyana to be an aldehyde-phenol; it gives a green coloration with ferric chloride; sodium liberates hydrogen from it. It dissolves in alkalis, and forms both alkyl and acid esters. According to its aldehyde character it reduces Fehling's solution and ammoniacal silver nitrate, and is converted by alcoholic potash, potash, and potassium permanganate into so-called diolic acid. This acid, however, has the formula  $C_{10}H_{14}O_3$ , and not  $C_{10}H_{16}O_3$ , as was to be expected if it is obtained by oxidation of diosphenol; its properties are not the same when prepared by different methods. Shinoyana was unable to prepare an oxime or sodium sulphite compound of diosphenol. Thus, there was no real proof of the presence of the aldehyde group.

As regards the eleoptene, the chief part of which boils at  $205^\circ$ — $210^\circ$  (Flückiger), nothing definite was known. The author has prepared the oxime and hydrazone of diosphenol and proved it to be a phenol-aldehyde. In the eleoptene he finds two substances—a ketone similar to menthone, and a reduced aromatic hydrocarbon.—A. C. W.

#### Pyramidone [Dimethylamido-antipyrine]. W. Fillehe. Pharm. Zeit. 1896, 812.

This is the name given to phenyl dimethyl dimethylamido-pyrazolone, or dimethylamido-antipyrine—

Pyramidone is a yellowish crystalline powder, soluble in 10 parts of water; the solution gives a violet-blue color-

ation with ferric chloride, soon turning violet and disappearing; with a nitrite and sulphuric acid a fugitive violet is produced (antipyrine gives a very stable green). Pyramidone has a similar physiological action to antipyrine, but smaller doses are required.—A. C. W.

#### Malarine. Pharm. Zeit. 1896, 865.

This is the condensation product of acetophenone and *p*-phenetidine,  $C_6H_5O.C_6H_4.N : C(CH_3)_2C_6H_5$ . Malarine crystallises in yellow plates melting at  $88^\circ$  C., is very soluble in warm alcohol, petroleum spirit, benzene, and chloroform; little soluble in cold alcohol and ether; insoluble in water. Warm hydrochloric acid resolves it into its constituents. Malarine has a peculiar odour, somewhat like that of nitrobenzene. It forms a citrate, soluble in 800 parts of cold water, and much more soluble in hot, which may be used as an antipyretic in doses of 0.5 gram. The solution of the citrate (1 in 800) gives a purple-red with ferric chloride; with bromine water, chromic acid, or iodine, a solution of 1 in 5,000 gives a light violet, changing into a deep purple-violet coloration.—A. C. W.

#### Mydrol [Iodomethylphenyl Pyrazolone]. Pharm. Centralh. 1896, 37, 718.

Iodomethylphenyl pyrazolone or mydrol is a white odourless powder with a bitter taste, soluble in cold water and alcohol, but insoluble in ether. Mydrol diminishes the heart's action and dilates the pupil, and is not toxic.

—A. C. W.

#### Caffeine, Compound of, with Mercuric Chloride. Dennhardt. Ber. pharm. Ges. 1896, 6, 284.

A compound,  $C_8H_{10}N_4O_2.HgCl_2$ , is precipitated when a solution of mercuric chloride is added to a solution of caffeine. It forms needles melting at  $245^\circ$  C. In consequence of the formation of this compound, caffeine cannot be extracted with ether from acid solutions containing mercuric chloride, but when excess of caustic soda is added, the double salt is decomposed, and ether then extracts the caffeine.—L. T. T.

#### Antipyrine, Compound of, with Mercuric Chloride. Hirsch. Ber. pharm. Ges. 1896, 6, 285.

When equal quantities of these two compounds are mixed in aqueous solution, a compound,  $C_{11}H_{12}N_2O_2.HgCl_2$ , is precipitated. Recrystallised from ether, this substance yields microscopic plates. No compound of antipyrine with mercurous chloride could be obtained.—L. T. T.

#### Kola Nuts. K. Dieterich. Apoth. Zeit. 1896, 11, 810.

Roasted kola nuts contain much less active principle than the dried nuts. A fluid extract from roasted nuts showed a specific gravity of 0.976, a dry residue of 11 per cent., and 1.04 per cent. of ash. A similar extract from dried nuts showed sp. gr. 0.984, dry residue 13.5 per cent., and ash 1.36 per cent.—L. T. T.

#### Drugs, Examination of some New. L. Spiegel. Chem. Zeit. 1896, 20, 970—971.

1. *Yohimbehe Bark*.—This bark comes from the Cameroons in the form of hard chocolate-brown pieces from  $\frac{1}{2}$  to 1 cm. in thickness. Extracts prepared in different ways gave alkaloid reactions; and physiological experiments indicated the presence of a strongly poisonous substance. A chemical examination showed that, in addition to a Bordeaux-red colouring matter, formed from the corresponding leuco compound by standing in alkaline solution exposed to the air, at least two alkaloids are present, only one of which, yohimbine, could be isolated in a pure condition. Pure yohimbine crystallises from alcohol in white needles melting at  $231^\circ$  C.; it is readily soluble in ethyl-, methyl-, and amyl-alcohol, ether, acetone, &c., but is insoluble in water. Analysis gave numbers agreeing with the formula  $C_{22}H_{32}N_2O_4$ , or  $C_{21}H_{28}N_2O_3 + \frac{1}{2}H_2O$ . This alkaloid forms a colourless solution with concentrated sulphuric acid; but if a crystal of potassium bichromate be added, a blue-violet-edged streak is produced, gradually changing to dirty green. Concentrated nitric acid forms a colourless solution, rapidly

becoming intensely yellow; this colour is not altered by heating, and on the addition of sodium hydroxide becomes orange-red. Characteristic reactions are likewise produced with Erdmann's reagent, phosphotungstic acid, phosphomolybdic acid, &c. A hydrochloride,  $C_{21}H_{25}N_2O_3 \cdot HCl$ , melting at  $28^\circ C$ , a sulphate, and picrate were also prepared. Physiological experiments showed that this alkaloid is extremely energetic.

The second alkaloid, *Yohimbine*, is easily soluble in 50 per cent. alcohol, and melts at  $105^\circ$ – $106^\circ C$ .

2. *Njalla-bean*.—The juice from these beans has an acid and bitter taste, and from it was isolated a white substance named *Njallin*, which decomposed at  $160^\circ C$ . The substance was very hygroscopic. It dissolves readily in hot water, glacial acetic acid, acetone, &c., is very slightly soluble in chloroform, and insoluble in benzene. In sodium carbonate it dissolves to a slightly yellow physiologically-active solution; on exposure to air it becomes red, and loses this activity. This is the case also when it is dissolved in sodium pyrophosphate solution, but in a solution of borax it remains unaltered for a longer period. The alcoholic solution gives a dirty brownish-violet coloration; with ferric chloride, the acetic acid solution showed this reaction sooner.

3. *New-Guinea Nuts (Illipe MacClayana)*.—These nuts form the seed of a large fleshy fruit. In appearance they resemble para-nuts, and are about twice as large, and have a smooth, brown, hard shell. The latter contains one, or perhaps several, alkaloids in small quantities. The author found that ether extracted from the dried kernel  $8\frac{1}{2}$  per cent. of an oily fat, from which a white crystalline substance separated on long standing. After removal of this fat, the extraction was continued with hot alcohol, and a body was obtained which, when purified, was very hygroscopic, and scarcely soluble in the ordinary solvents. It melted at  $165^\circ C$ , and appears to have the formula  $C_{17}H_{35}O_{10}$ . The author names this body *Macleyin*.

*Macleyin* is coloured, first, orange-red, and finally rose-red, by concentrated sulphuric acid; a crystal, of potassium bichromate causes the colour to become violet. Concentrated nitric acid dissolves it in the warm without coloration, whilst fuming nitric acid produces an acid insoluble in water, but separating in a crystalline condition from alcohol. It melted at  $200^\circ C$ . *Macleyin* also forms a crystalline benzoyl and acetyl derivative, the latter melting at  $124^\circ C$ . Physiological examination showed the properties of *macleyin* to be very strongly marked.—J. L. B.

*Tannin Extracts, The Manufacture of.* Fuchs and Schiff. Chem. Zeit. 20, [93], 926.

THE first liquors obtained in the manufacture of tannin extracts contain, besides tannic acid, gummy and resinous matters in suspension, some tannin soluble with difficulty, which separates out in the cold liquor, and further, certain colouring matters. To eliminate these undesirable constituents, 1,000 litres of the liquor, at a temperature of  $50^\circ C$ , were mixed with 0.94 kilo. of dissolved albumin, and the temperature was then raised to  $60^\circ C$ . By this treatment all the above-named impurities were precipitated, but it was also found that at the same time upwards of 12 per cent. of the total tannic acid contained in the liquor was precipitated by the albumin. For this reason this method must be described as irrational, and the clarification of the tannin liquors by mechanical means, appears preferable.

## XXI.—PHOTOGRAPHY.

*Photography in Colours.* Sir H. Trueman Wood. J. Soc. of Arts, 1897, 45, 158–159.

A PROCESS suggested by Dr. Adrian Dansac, and developed by M. Villedieu Chassagne. Four solutions are used, the nature of which the inventor has not disclosed. A negative is taken on a gelatin plate prepared by treatment with one of the solutions, developed and fixed as usual, and from this a transparency or paper print is taken on glass or paper prepared with the same solution. Neither negative nor positive shows any trace of colour. The positive is then washed over successively with the three other solutions, blue, green, and red respectively, and takes up the appropriate colours in the appropriate parts. The process was demonstrated by M. Chassagne in King's College Laboratory to Sir H. Trueman Wood, Prof. J. M. Thomson, Mr. Herbert Jackson, and Capt. Abney, when, it is said, a bunch of flowers and other test objects were successfully photographed in their natural colours.—J. T. D.

## PATENT.

*Sensitised Paper suitable for Photographic Purposes, Impts. in the Manufacture of.* W. Friese-Greene, London. Eng. Pat. 24,440, Dec. 20, 1895.

INSTEAD of coating paper with sensitising material, the latter is added to the paper pulp before it has been formed into paper; or, preferably, by applying the sensitising material to the surface of the "paper-web" just after it had been formed, and whilst it is still moist.—R. B. P.

## XXII.—EXPLOSIVES, MATCHES, Etc.

### PATENTS.

*Explosives [for Guns, &c.], and in Apparatus therefor; Impts. in the Manufacture of.* Hudson Maxim, London. Eng. Pat. 16,862, Sept. 9, 1895.

IN order to obtain low pressures, which shall be sustained during the travel of the projectile along the chase of the gun, a special form is given to the explosive charge; this forms the subject of the invention.

The explosive material is first made into a sheet of suitable size and thickness, with a number of holes or indentations upon one surface, but which do not pass right through the sheet.

The sheet is then bent into a hollow cylinder, with the indentations on the inner side.

The charge is ignited on the inside, and the outer wall of the cylinder is pressed against the wall of the powder chamber, so that combustion can only take place over the inner surface of the cylinder.

As combustion proceeds, the area exposed to its action constantly increases, whereby the pressure in the gun is maintained as the projectile is driven along the chase.

—R. B. P.

## XXIII.—ANALYTICAL CHEMISTRY.

## APPARATUS, ETC.

*Ebullioscope, A Modified Form of the.* H. W. Wiley.  
J. Amer. Chem. Soc. 1896, 18, 1063—1067.

The chief difficulties attending the use of the ebullioscope for the determination of alcohol in wine and beer have been (1) that the reading of the thermometer is influenced, not only by the temperature of the vapour emitted, but also by the initial boiling point, which is affected by the dissolved matters contained in the liquid; (2) that it is difficult to ensure the continuous evolution of a vapour containing a definite percentage of alcohol; (3) that when the condensed vapours, as is usually the case, are returned through the apparatus and come into contact with the uncondensed vapours, the reading of the thermometer is affected; and (4) that the variation of atmospheric pressure renders necessary a frequent checking of the instrument with pure water. These defects the author proposes to remedy by means of the apparatus here described.

The flask F is closed by an india-rubber stopper, through which pass the thermometer B and a tube leading to the condenser D. The vapours given off are condensed in D and returned to the flask, entering the latter below the surface of the liquid. The glass cylinder E protects the apparatus from the influence of external temperature, and this cylinder rests upon a disc of asbestos. The flask covers a hole in the centre of the asbestos disc, which is a little smaller than the bottom of the flask. The cylinder is covered at the top with a disc of rubber cloth. The thermometer C indicates the temperature of the air between F and E, and the reading of B should always be made at a given temperature, as indicated by C. The long tube leading from the top of D is open at its lower end, in order to secure atmospheric pressure in F, and to prevent diffusion of the alcohol vapours through D. The thermometer B is set, in

the first place, by putting the bulb in water containing 16 grms. of common salt in 100 c.c. When the water is fully boiling, the excess of mercury is removed from the column into the receptacle A; and then, on placing in ordinary boiling water, the column of mercury will be found a little above the 5° mark, by A.

The liquid to be tested should not contain more than 5.5 per cent. of alcohol, and stronger liquids are diluted before testing. The temperature of C is brought to about 90° C. in ten minutes, and after boiling for a few minutes, B indicates a constant temperature, and readings are taken at intervals of about 30 seconds for two minutes. The reading of this thermometer is arbitrary, but the degrees indicated are Centigrade. When the thermometer is graduated so that it indicates about 5° on the scale in the vapour of boiling water, it will be found that the presence of 1 per cent. by volume of alcohol causes a depression of about 0.8° in the boiling point. The reading of the thermometer is facilitated by covering the bulb with a test tube containing water.

To avoid the correction for barometric pressure, it is merely necessary to use at the same time a similar apparatus containing boiling water, and to read the thermometers in the two flasks at the same instant.—R. B. B.

*Temperature Determinations. [Le Chatelier Pyrometer].*

See under VIII., page 143.

## PATENT.

*Fire-damp or other Noxious Gas or Gases in the Atmosphere of Mines and other Places; Method of and Apparatus for Detecting and Indicating the Presence of.*  
E. L. Mayer, Billiter Square, London, and G. Bush, Gracechurch Street, London. Eng. Pat. 18,188, Sept. 28, 1895.

THE presence of fire-damp or other noxious gases in mines or other places is detected and indicated by causing such gas or gases to generate, by means of a gas battery, charges of static electricity that are caused to control means or apparatus whereby a visual or audible signal, or both, are brought into operation. The gas battery consists of a hermetically closed box filled with pure air, through the walls of which are passed a number of porous non-conducting blocks, as fire-clay, &c., impregnated with an electrolyte, as sulphuric acid, and connected up in series. The box is exposed to the noxious gas, and the outer ends of the blocks, which generally project, being also exposed, set up a charge of static electricity in the conductors connected therewith. The specification contains descriptions and drawings of a large number of alternative forms of apparatus which may be employed to make use of this electricity to control the various signals. The following distinct forms are illustrated and described:—

(1) A condenser, (2) an ordinary quadrant electrometer, (3) a Kelvin quadrant electrometer, (4) a Bohnenberger electro-scope, (5) a condenser embodying the principle of a Bohnenberger electro-scope, and (6) an ordinary gold-leaf electro-scope, which is preferably used in connection with two condenser plates. The signals operated may be audible ones, or electric lumps may be brought into use, or put out, or the light rendered much less. This last is especially useful in mines. The light of a lamp may act upon a selenium cell to produce a signal; and a special selenium cell is described for this purpose, consisting of two metallic gratings connected together by selenium, and so arranged that a considerable surface of selenium can be exposed to the rays of light.—R. S.

INORGANIC CHEMISTRY.—  
QUANTITATIVE.

*Analytical Chemistry, The Importance in, of the Ionic Dissociation Theory of Arrhenius.* F. W. Küster.  
Zeits. f. Elektrochem. 3, (1896), 233—236 and 257—260.

*Formaldehyde as a Reducing Agent in Analysis.*B. Grützner. Arch. Pharm. 1896, **234**, 631.

**Chloric Acid.**—On adding silver nitrate and formaldehyde to a solution of potassium chlorate and acidifying with nitric acid, the whole of the chlorine is converted into silver chloride, thus:—

$\text{HClO}_3 + 3\text{CH}_2\text{O} + \text{AgNO}_3 = 3\text{CH}_2\text{O}_2 + \text{AgCl} + \text{HNO}_3$ .  
The reaction is hastened by warming. In this way chloric acid may be conveniently determined, either gravimetrically or volumetrically. If the chlorate contain chlorides, these may first be estimated by titration with  $\frac{1}{10}$  N silver solution, and the total chlorine is determined after the addition of formaldehyde and nitric acid.

**Bromic Acid** may be determined in the same way, but the mixed solution must be heated for 2—2½ hours on a water-bath to complete the reaction.

**Iodic Acid** is not reduced; periodic acid and perchloric acids are only reduced in very small proportion (the former to iodic acid). The reaction of formaldehyde with potassium chlorate may be used for the estimation of the former by adding to the aldehyde some chlorate, together with a few c.c. of nitric acid and silver nitrate solution, and weighing the resulting silver chloride.—W. G. M.

**Sulphates, Decomposition of, in Analysis, by Ammonium Chloride.** M. Chikashige. J. Coll. of Science, Imp. University, Japan, **7**, iv., 251—252.

In the separation of barium from magnesium and alkali salts, the small quantity that is left in solution by ammonium carbonate is precipitated by the addition of 3 or 4 drops of dilute sulphuric acid. The author contradicts the statement of Fresenius in a footnote to § 153 A. of the seventh edition of his "Quantitative Analysis," that gentle ignition for the purpose of driving off ammonium salts will also effect the removal of any small quantity of sulphuric acid which may remain after precipitating the barium, sulphates of the alkalis being converted into chlorides on ignition with a large proportion of ammonium chloride. It was proved by experiment that very little, if any, of the sulphuric acid is driven off by ignition at a temperature barely approaching red heat. (See this Journal, 1895, 629.)—A. S.

**Limestones, Estimation of Iron and Alumina in.** Désiré de Paepé. Chem. Zeit. 1896, **20**, 1001.

The very convenient method of separating iron from alumina by means of ammonium sulphide, in presence of ammonium tartrate, is prejudiced by the presence of much lime. The present method is proposed as a rapid and convenient one for attaining the object in view, in spite of the condition named.

The limestone (5 to 10 grms.) is treated in a covered beaker with strong hydrochloric acid and boiled for five minutes. The diluted and filtered solution is treated with a few drops of nitric acid and heated to boiling. When cold, an excess of ammonia is added and the whole boiled until the odour of ammonia becomes slight. It is then filtered, washed, and made up to 500 c.c. In 50 c.c., lime and magnesia are determined.

The ammonia precipitate is dissolved in hydrochloric acid, the solution diluted to 125 c.c. Alumina and iron are determined in 50 c.c., whilst iron alone is determined in another 50 c.c., as follows:—10 per cent. of tartaric acid solution (5 or 10 c.c.), then an excess of ammonia, and finally, a slight excess of ammonium sulphide are added. The whole is heated moderately for 2—3 hours, filtered, and washed with boiling distilled water containing a trace of ammonium sulphide. This should be done quickly, and the funnel covered so as to exclude air as much as possible. The precipitate is redissolved in hydrochloric acid, treated with a few drops of nitric acid, and heated to boiling. The iron is again precipitated with ammonia, filtered, washed, &c., and weighed.—N. H. J. M.

**Alkalis and Alkaline Carbonates, Volumetric Estimation of, with Phenolphthalein and Methyl-orange as Indicators.** F. W. Küster. Zeits. anorg. Chem. 1896, **13**, 127.

In the titration of mixed solutions of alkalis and alkaline carbonates, the only satisfactory method, it is said, is that

recommended by Winkler, *viz.*, the barium chloride method, with direct titration of the solution and precipitate, with methyl-orange as indicator.

Methyl-orange (contrary to previous statements) is decidedly coloured by carbonic anhydride. For accurate work it is essential to have for comparison of "normal tint," a solution of the indicator of like strength and saturated with carbonic anhydride. Phenolphthalein is coloured by alkaline carbonates in weak solutions, and is therefore not reliable as an indicator.—L. T. T.

**Phosphoric Acid in Potable Waters, Determination of.** C. Lepierre. Bull. Soc. Chim. 1896, **15**, [23], 1213—1217.

The maximum limit of phosphoric anhydride in potable waters was fixed at 0.5 mgrm. by the congress of Brussels, this number probably indicating sewage contamination. The author has devised a colorimetric method based upon the yellow colour of a solution of ammonium phosphomolybdate in nitric acid. This colour is found to be exactly proportional to the amount of phosphoric acid present (at least up to 30 mgrms.  $\text{P}_2\text{O}_5$  to the litre) when the temperature is uniform. A series of standard tubes is prepared containing known quantities of phosphoric acid in the form of ammonium phosphomolybdate. In testing a water, a litre is evaporated with the addition of nitric acid, the residue heated sufficiently to render the silica insoluble, redissolved in nitric acid, tested with molybdate, and the colour compared with the standard tubes. Silica, if not removed, interferes with the reaction.—A. K. M.

**Boric Acid, Volumetric Determination of.** G. Jørgensen. Zeits. f. angew. Chem. 1897, **5**. (See also this Journal, 1896, 742—743.)

The method is based on the facts that in aqueous solutions boric acid behaves like an excessively weak acid, whilst in presence of mannite or glycerin it is capable of neutralising caustic soda. The author finds that, in aqueous solution, phenolphthalein is reddened when about 1 molecule of NaOH is added to  $6\text{B}(\text{OH})_3$ ; in presence of excess of glycerin the end point corresponds fairly accurately to the formation of  $\text{NaBO}_2$ .

The method is expected to be of service in the determination of the small quantities of boric acid which are sometimes added to foods as a preservative. As an example of its application, three separate quantities of milk of 100 c.c. each were treated with 0.39, 0.1, and 0.0 gm. of boric acid respectively: after adding a little  $\text{Na}_2\text{CO}_3$  these were evaporated to dryness and incinerated; the residue was taken up with dilute sulphuric acid, filtered, and titrated with caustic soda, using phenolphthalein as indicator. About 20 c.c. of glycerin were then added (causing the red coloration to disappear), and caustic soda run in until it appeared again. From the amount of caustic soda used in the second titration, the quantity of boric acid is calculated, 35 grms. of  $\text{B}_2\text{O}_3$  corresponding to 850 c.c. of normal alkali. It is, however, preferable to titrate a solution containing a known quantity of boric acid side by side with that under examination, treating both solutions in exactly the same way; this eliminates some uncertainty which exists owing to the end point being deficient in sharpness; it also makes it unnecessary to know the strength of the caustic soda solution.

In the samples of milk above mentioned the author found 0.388, 0.107, and 0.013 gm. of boric acid.—T. E.

**Perchlorates in Chili Nitrate of Soda; Detection and Estimation of.** B. Sjöllema. Chem. Zeit. **20**, 1002.

**Detection of Perchlorates in Chili Nitrate of Soda.**—20 grms. of nitrate of soda are dissolved in water (20 c.c.), cooled, and gradually treated with strong sulphuric acid (15 c.c.). The nitric acid is then reduced with hydrogen sulphide and the sulphur removed by filtration. On adding a solution of rubidium chloride to the filtrate, a crystalline precipitate is formed, if sufficient perchlorate be present. Potassium acetate may be employed, but the reaction is less sensitive. The crystals are washed with a little water and dilute alcohol, and ignited with a little sodium nitrate or carbonate; the product is dissolved in dilute nitric acid and tested for chloride.

Another method is to distil the solution after addition of sulphuric acid, and to treat the last portions of the distillate with rubidium chloride, either directly or after precipitation of the sulphuric acid.

*Estimation of Perchlorates in Nitrate of Soda.*—The substance (10 grms.) is ignited in a platinum crucible, or better, in a conical platinum flask and the chlorine estimated by titration, using Volhard's method. From the results so obtained, the amount of chlorides in the sample before ignition is deducted. Owing to the irregular distribution of perchlorates in Chili nitrate of soda, it is desirable to dissolve a large amount (100 grms.) of the substance in water (500 c.c.); in 50 c.c. of the solution, the chlorides are determined directly, whilst a second 50 c.c. are evaporated to dryness and ignited.—N. H. J. M.

*Bismuth and Lead, The Separation of.* A. L. Benkert and E. F. Smith. J. Amer. Chem. Soc. 1896, **18**, 1055—1056.

Bismuth may be completely separated from lead by precipitation of the former as basic formate. This is effected as follows:—A nitric acid solution of the mixed nitrates is almost neutralised with sodium carbonate, and a considerable quantity of sodium formate is then added, together with a few drops of aqueous formic acid. The mixture is heated to boiling and boiled for five minutes; the precipitate is then allowed to subside, but filtered while still hot. The precipitate of basic formate is washed with hot water, dissolved in dilute nitric acid, and precipitated with ammonium carbonate. The ignited bismuth trioxide contains a small quantity of lead, and to effect complete separation it is dissolved in nitric acid, almost neutralised with sodium carbonate, and precipitated as before. On the second ignition no lead is found in the residual bismuth trioxide.

—R. B. B.

*Vanadium and Arsenic, The Separation of.* C. Field and E. F. Smith. J. Amer. Chem. Soc. 1896, **18**, 1051—1052.

WHEN arsenates and vanadates are heated in an atmosphere of hydrochloric acid gas, both acids are volatilised. If, however, the dry sulphides of arsenic and vanadium are treated in this manner, arsenic trisulphide is completely expelled, whilst brown vanadium sulphide is not altered at temperatures below 250° C.

These facts may be utilised in the analysis of *vanadinite*. The finely divided mineral is placed in a porcelain boat and heated in a combustion tube in a current of hydrochloric acid gas. Vanadic and arsenic oxides are expelled; lead phosphate and chloride remain behind. The oxides are made alkaline and digested with ammonium sulphide, and the sulphides are set free by a dilute acid. These sulphides are washed and dried, separated by hydrochloric acid gas as above, converted into oxides, and weighed.—R. B. B.

*Arsenic, Volumetric Estimation of.* E. Szarvay. Ber. 29, [18], 2900—2902.

THE arsenic is precipitated from solution as sulphide in the usual way, and the liquid filtered through an asbestos filter consisting of a combustion tube, 80—100 cm. long, having a plug of asbestos of suitable quality about 15 cm. from its upper end. The tube is held vertically above a beaker, and the liquid is best poured directly on to the asbestos by means of a long funnel. Having washed the precipitate with water, and then with alcohol and ether to expedite the drying, a stream of dry air or carbon dioxide is passed through the gently inclined tube, which may be warmed either in a water bath or by means of a flame, cautiously applied. It is necessary to dry the tube thoroughly, to prevent sulphur dioxide from being subsequently retained. A good plug of glass-wool is now placed in the tube, about 10 cm. from the other end; a stream of oxygen is passed through the tube, which is then kept heated to gentle redness immediately behind the asbestos plug; and by means of another flame the sulphide is heated, care being taken that it is made to burn away gradually, and not all at once. Arsenic trioxide sublimes and condenses beyond the glowing ring; if the sublimate is tinged yellow, the unburnt

sulphide causing this is driven back to the asbestos plug, the stream of oxygen being meanwhile stopped, and, on re-starting the stream of gas, the sulphide can be completely burnt to oxide. The sulphur dioxide is next driven out of the tube by a stream of air, and the cold tube held obliquely, glass-wool end uppermost, whilst sodium hydrate solution (about 30 to 40 c.c. of 10 per cent. solution) is poured down it to dissolve out the arsenic trioxide. Having washed it down with 400—500 c.c. of water, the solution is acidified slightly with HCl, saturated with excess of sodium bicarbonate, and titrated iodometrically, the iodine solution being standardised against sublimed arsenic trioxide. The test analyses quoted are very satisfactory.—H. B.

*Copper: Electrolytic Analysis for Technical Purposes: Estimation of Arsenic, Antimony, Sulphur, and Foreign Metals.* A. Hollard. Comptes rend. 1896, **123**, [24], 1063—1065.

THE solution from which the copper has been removed, is evaporated almost to dryness, taken up with a little hydrochloric acid, made up to about 200 c.c., and heated to 70°—75°; hydrogen sulphide is then passed through till quite cold, and the solution filtered after 24 hours.

*Precipitate.* (arsenic, antimony, traces of lead, and, it may be, of copper) is well washed, treated with ammonium sulphide, and filtered; the filtrate is evaporated, oxidised by hydrochloric acid and potassium chlorate, the arsenic precipitated as magnesium ammonium arsenate, and the antimony in the filtrate from this converted into sulphide, dissolved in alkaline sodium sulphide, and deposited by electrolysis.

*Filtrate*, (iron, nickel, and cobalt) is boiled down, treated with nitric acid to peroxidise the iron, evaporated till fumes of sulphuric acid appear, and redissolved in water.

Slight excess of ammonia is now added to precipitate the iron (which is redissolved and reprecipitated to separate traces of nickel or cobalt), which can be determined volumetrically. To the filtrate, ammonia and ammonium sulphate are added, and the nickel and cobalt are deposited electrolytically.

To determine silver, the deposited copper (if rich in silver), or a new sample of 10 grms. to 50 grms., is dissolved in nitric acid, the silver precipitated as chloride, the chloride redissolved and reprecipitated, then dissolved in potassium cyanide, and submitted to electrolysis.

To determine lead, 10 grms. are dissolved in a large excess of nitric acid, and the lead deposited by electrolysis at the anode as PbO<sub>2</sub>.

Sulphur is determined by dissolving a sample in aqua regia and proceeding in the ordinary way.—J. T. D.

*Manganese and Tungstic Acid, The Separation of.* W. T. Taggart and E. F. Smith. J. Amer. Chem. Soc. 1896, **18**, 1053—1054.

THE two methods tried by the authors have both proved insufficient to effect a quantitative separation of manganese from tungstic acid. By digestion with yellow ammonium sulphide in presence of ammonium chloride, and conversion of the manganous sulphide into oxide, the weight of the latter found, is too great, tungstic acid apparently adhering to the metallic oxide. In the second method the mixture was digested with a strong solution of potassium carbonate, and, in this case, ignition of the manganese carbonate to oxide gave too low a percentage of manganese. The authors suggest fusion with an alkaline carbonate as a possible solution of the difficulty.—R. B. B.

*Iron and Alumina, Estimation of, in Phosphates and Superphosphates.* Von Gruber. Zeits. f. angew. Chem. 1896, **11**, 741—742.

THE solution for estimating iron and alumina separately, is prepared as follows:—The crude phosphate or superphosphate (5 grms.) is heated with water (150 c.c.) and strong hydrochloric acid (20 c.c.), in a covered dish on a water-bath, until the phosphates are dissolved. It is then evaporated to dryness, the residue redissolved by heating with acid and water, and, when cold, diluted to 500 c.c. It is then filtered and aliquot portions used for estimating alumina and iron.

**Estimation of Alumina.**—50 c.c. of the solution (= 0.5 grm. of substance) are heated in a 200-c.c. flask and treated with 20 per cent. caustic soda until a slight precipitate is formed; more soda (30 c.c.) is then added, the whole heated to boiling, and kept for 10 minutes in a warm place, being frequently shaken. The solution is diluted to 200 c.c. and filtered through a dry filter. 100 c.c. of the filtrate are slightly acidified, heated to boiling, treated with an excess of ammonia, and boiled. As soon as the precipitate (aluminium phosphate) has settled, it is filtered, well washed, dried, and ignited. The weight multiplied by  $41.8 \times 2$  gives the percentage of alumina.

**Estimation of Iron.**—100 c.c. of the solution, contained in a 250-c.c. flask, are treated with pure zinc and the necessary amount of dilute sulphuric acid. After about an hour, the solution is cooled, the flask filled to the mark, 50 c.c. of the filtered solution run into a beaker containing 50 c.c. of 20 per cent. sulphuric acid and 200 c.c. of water, and titrated with permanganate. Another 50 c.c. of the solution are added, and again titrated. This is repeated a third and, if necessary, a fourth time; but the third titration generally agrees with the second.

Very good results are obtained by the methods, which are, it is said, simpler and more rapid than Glaser's.

—N. H. J. M.

### ORGANIC CHEMISTRY.—QUALITATIVE.

**Analytical Chemistry, The Importance in, of the Ionic Dissociation Theory of Arrhenius.** F. W. Küster. Zeits. f. Elektrochem. **3**, (1896), 233—236 and 257—260.

See under XI. A., page 148.

**Quinine Salts, Potassium Chromate, a Test for the Purity of.** J. E. de Vrij. A pamphlet.

ONE GRM. of the sample is heated with 40 c.c. of water until just dissolved. When testing the commercial sulphate, the solution should be faintly alkaline to red litmus paper. Six cubic centimetres of a 5 per cent. solution of perfectly neutral potassium chromate are now added, and the separation of normal quinine chromate, which sets in immediately, is completed by cooling to 15° C. The liquid is now filtered through glass-wool, the filtrate being passed through the filter a second time. After having made quite sure that further addition of the chromate solution gives no more precipitate, the liquid is introduced into a test-tube of about 50 c.c. capacity and mixed with 9—10 drops of a 5 per cent. solution of caustic soda. After allowing it to stand over night, the tube is examined, and if the sample of quinine salt be really pure, not the least trace of precipitate should be visible. When, however, the sample contains an admixture of cinchonidine, quinidine, cinchonine, or hydroquinine, a more or less copious precipitate is obtained, which in careful hands may even be made the basis of a quantitative estimation of the inferior alkaloids, by the well-known method of comparing with standard samples.

The quinine chromate can be easily converted into the pure alkaloid by dissolving it in 100 parts of boiling water and pouring the liquid into soda solution.—L. de K.

**Formaldehyde, Detection of Small Quantities of.** L. Kentmann. Pharm. Gen. Anz. 1896, **8**, 356. Chem. Zeit. **20**, [104], 313.

0.1 GRM. of morphine hydrochloride is dissolved in 1 c.c. of strong sulphuric acid in a test-tube, and an equal volume of the solution to be examined is added to it without mixing; in the presence of formaldehyde the aqueous solution will become clear red-violet in colour after the lapse of a few minutes. The reaction is sensitive to 1:5,000—6,000. The author recommends this test as a reaction for the identification of the German Pharmacopœia III.—W. G. M.

**Alkaloids, Characterisation of, by their Micro-Crystalline Precipitates.** Vadam. J. Pharm. Chim. 1896, **4**, 485.

THE microscopic examination of alkaloids has the advantages that any method of extraction may be used, and that, once the alkaloid residue is obtained, a single drop of

dilute solution is sufficient for each reaction; thus some quantity of the residue may be preserved for other conclusive tests.

The residue of alkaloid having been obtained and weighed, is dissolved in 2 per cent. hydrochloric acid to give a solution containing about 0.5 per cent. of alkaloid, one drop is placed in the hollow of each of a dozen slides, the drop is mixed with one drop of the reagent, and a coverslip placed over. After half an hour the slides are examined under a low power. The following reagents are used.—1. Mayer's reagent: 13.56 grms. mercuric chloride, 19.8 grms. potassium iodide, made up to 1 litre. 2. Bouehardat's reagent: 10 grms. iodine, 20 grms. potassium iodide, 500 grms. water. 3. Saturated solution of picric acid. 4. Gold chloride, 5 per cent. solution. 5. Platinum chloride, 5 per cent. solution. 6. Schultze's reagent: solution of sodium phospho-antimoniate. 7. Scheibler's reagent: solution of sodium phosphotungstate. 8. Lepage's reagent: 10 per cent. cadmium iodide solution. 9, 10, and 11. Saturated solution of potassium bichromate, ferrocyanide, and ferricyanide. 12. Sodium nitroprusside, 10 per cent. solution.

In each case there may be a crystalline precipitate, an amorphous precipitate, or no precipitate at all. By means of these reactions in any one case all the alkaloids will have been eliminated except some two or three; the particular one present may then be recognised by the crystalline forms observed.—A. C. W.

**Pyrimidone.** [Dimethylamido-Antipyrine.] W. Fühne. Pharm. Zeit. 1896, 812.

See under XX., page 160.

### ORGANIC CHEMISTRY.—QUANTITATIVE.

**Starch-Hydrolysis by Diastase, On the Experimental Methods employed in the Examination of the Products of.** H. T. Brown, G. H. Morris, and J. H. Millar. Proc. Chem. Soc. 1896, [172], 241.

THE paper is divided into the following sections:—(1) The determination of solids from solution-density; (2) determination of specific rotatory power; (3) the relation of  $[\alpha]_D$  to  $[\alpha]_D$ ; (4) determination of empic reducing power; (5) limits of accuracy of the methods.

The author states that this account is a preface to a series of papers dealing with the question of starch-hydrolysis, and is a critical review of the experimental methods which have been employed by different observers who have approached this subject. An attempt has also been made to remove the misunderstanding which still exists as to the relations of the different systems of notation.

The determination of the total solids from the density of the solution by the employment of the "divisor" method admits of great accuracy if the solution-densities of the pure substance have been previously determined.

For mixed starch hydrolytic products, the divisor for equal concentrations increases with the specific rotatory power, and in such a regular manner that when the value of R is known, the divisor at any given concentration can be calculated. From the relation which this divisor bears to the divisor of the apparent maltose present in the mixed hydrolytic products, it is deducible that the divisor for the amylin constituent is constant for equal concentrations, even in starch products of very different grades of hydrolysis.

In the section on specific rotatory power, the methods of exact determination are discussed. As the dispersive power of cane sugar is sensibly different from that of dextrose and starch hydrolytic products obtained by diastase, the factors for the conversion of  $[\alpha]_D$  into  $[\alpha]_D$  are not identical in these cases. Much confusion of these relations has also been introduced by the unrecognised fact that  $[\alpha]_D$  has been referred to two distinct rays in the yellow of different refrangibility.

The cupric reduction of maltose and of the products of starch-transformation is constant only when the conditions of experiment are identical.

*Dextrose, Levulose, and Invert Sugar, The Solution Density and Cupric-Reducing Power of.* H. T. Brown, G. H. Morris, and J. H. Millar. *Proc. Chem. Soc.* 1897, [173], 4—5.

THE authors have extended the methods described in their previous paper (*Proc. Chem. Soc.* 1896, 12, 241) to the examination of the solution density and cupric-reduction of dextrose, levulose, and invert sugar. They find that the solution densities of the two former differ considerably with the same concentration of the solution, but that the volume occupied in solution by a unit of weight of each is less at lower than at higher concentrations, consequently the divisor to be applied to the specific gravity decreases with the concentration. The solution density of invert sugar was calculated from those of dextrose and levulose, and the results so obtained were confirmed at various points by direct experiments.

They also find that the cupric-reducing powers of the three sugars, when determined under their standard conditions, are, for dextrose,  $\kappa = 117$  to 105; for levulose,  $\kappa = 107.5$  to 101; and for invert sugar,  $\kappa = 111$  to 103. The higher numbers are obtained when a small amount of cuprous oxide is precipitated, and the lower when reduction is carried nearly to the maximum. When the experimental numbers are expressed in the form of a curve, it is found that at the one end, taking the cupric reduction of dextrose at 100, levulose is represented by 91.3, and invert sugar by 94.2; at the other end of the curve, the ratio is 100, 94.6, and 97.5; whilst at an intermediate point, which corresponds to the amount of cuprous oxide usually reduced, the relation is, dextrose, 100; levulose 92.3; and invert sugar, 96.15.

*Maltose and of Soluble Starch, On the Specific Rotation of.* H. T. Brown, G. H. Morris, and J. H. Millar. *Proc. Chem. Soc.* 1896, [172], 242.

THE authors' determinations of the specific rotatory power of maltose at a temperature of  $15.5^\circ$  do not confirm the statement of Meissl that the values of  $[\alpha]_D$  vary with the concentrations between 2 and 20 per cent., but confirm the general statement of Ost that between these limits the specific rotatory power is constant. At higher concentrations than 20 per cent., the specific rotatory power diminishes slightly.

The actual results point to a value of  $[\alpha]_D = 137.93^\circ$ , which is sensibly greater than Ost's value of  $137.46^\circ$  at  $15.5^\circ$ .

This discrepancy is due to the fact that Ost employed weighed quantities of hydrated maltose which had been dried in a desiccator over sulphuric acid. The authors find that even after six weeks' drying in this manner, hydrated maltose contains 0.46 per cent. more water than corresponds to  $C_{12}H_{22}O_{11} \cdot H_2O$ . If Ost's numbers are corrected for this they give values, up to 20 per cent. concentrations, of  $[\alpha]_D = 138.12^\circ$  at  $15.5^\circ$ , a result almost exactly identical with that of the authors.

The specific rotatory power of soluble starch for concentrations of 2.5 to 4.5 per cent. is, at  $15.5^\circ$ ,  $[\alpha]_D = 202.0^\circ$ .

*Starch-Hydrolysis by Diastase, On the Relation of the Specific Rotatory and Cupric Reducing Powers of the Products of.* H. T. Brown, G. H. Morris, and J. H. Millar. *Proc. Chem. Soc.* 1896, [172], 243.

WHEN starch is transformed by diastase, a certain relation is always found to subsist between the cupric reduction and specific rotatory power of the hydrolytic products. This relation can be expressed in such a manner as to be entirely independent of any view we may hold as to the true nature of the transformation products, and it is of so exact a nature that if one property is known the other can be predicted with certainty. This is true not only for the mixed hydrolytic products, but for any fractionated portion of them.

The authors regard this fact as lying at the root of the whole question of starch-hydrolysis, and, as it is still not admitted by most continental workers, they bring forward a large amount of fresh evidence which they regard as absolutely conclusive.

The properties of soluble starch being  $R = 0$ ,  $[\alpha]_D = 202^\circ$ , and of maltose,  $R = 100$  and  $[\alpha]_D = 138.0^\circ$ , then the relation of specific rotation and cupric reduction for any mixture or fractionation of the starch-hydrolytic products will be expressed by  $[\alpha]_D = 202 - 0.64 R$ .

The authors have examined the published results of C. J. Lintner and of Ost, both of whom have denied the existence of any relation between  $[\alpha]_D$  and  $R$ , and find that, when rightly interpreted, they, for the most part, strictly conform to the law of relation expressed above.

*Alkaloidal Extracts, The Separation of.* C. Platt. *J. Amer. Chem. Soc.* 1896, 18, 1104.

THE author has found the apparatus here illustrated of great value in effecting the rapid separation of the emulsions often met with in the analysis of alkaloids; as, for example, in the petroleum spirit and benzene extractions of

Dragendorff's method. The filtering tube is 19 cm. in length, the upper 12.5 cm. having an inside diameter of 14 mm., and the lower contracted portion an inside diameter of 3 mm. A stout platinum wire, bent at the upper end, passes through the constricted portion of the tube to the bottom of the 8-oz. flask. The tube is packed with washed cotton to a depth of about 4 cm., and the apparatus, when connected with a filter-pump, is ready for use.—R. B. B.

*"Sulphur Oils," so-called; Estimation of Free Sulphur in.* G. Morpurgo. *Pharm. Post.* 1896, 29, 501.

OILS commercially extracted by means of carbon bisulphide often contain traces of sulphur resulting from the impurity of the bisulphide. To estimate such sulphur, a weight of 25 grms. of the oil is saponified with caustic soda, then mixed with 10 c.c. of a 10 per cent. solution of lead acetate, and acidified with a few drops of acetic acid. After thoroughly shaking the mixture, the supernatant liquor is withdrawn from the precipitate of free fatty acids, lead sulphide, and lead soap; the precipitate is then covered with 50 c.c. of 95 per cent. alcohol, and strongly acidified with acetic acid, and the mixture is warmed on the water-bath until the lead sulphide is deposited. The fatty acids set free, are removed by means of alcohol, and the residue is thoroughly washed, first with warm but very dilute acetic acid, and then with a 5 per cent. solution of ammonia, after which it is collected on a filter, washed with water, dried, and weighed as PbS.

—W. G. M.

*Glycerin, New Method of Estimating.* Bordes and de Raczowski. *Comptes rend.* 1896, **123**, [24], 1071—1072.

The method is based on one of Nielonx for estimating small quantities of alcohol. When potassium bichromate is caused to act upon glycerin in presence of sulphuric acid, formic acid and carbonic acid are formed. A solution of potassium bichromate of 48 grms. per litre is added to 5 c.c. of the sample, mixed with 2 c.c. of sulphuric acid. The end of the reaction is marked by the change of tint (to green), when a drop of unchanged bichromate mixes with the titrated solution. Each c.c. of the bichrome solution corresponds to 1 grm. of glycerin per litre. The method is only available for solutions containing under 2 grms. of glycerin per litre; stronger solutions must be diluted. The solutions are so adjusted that 0.1 c.c. more or less, of bichromate give either a yellowish-green or bluish-green tint.—J. T. D.

*Pentosans, Proportion of, in Cotton Wool.* H. Suringar. *Chem. Zeit. Rep.* 1896, 290.

The percentage of pentosans in cotton wool is determined by the furfuraldehyde resulting from a phloroglucinol precipitate obtained from wadding. The proportion is very small, and when, therefore, large quantities of gummy substances are found in purified wadding, they must have resulted from the hydrolysis of the cellulose itself.

—W. G. M.

*Invert Sugar, The Determination of.* A. Leys. *J. Pharm. Chim.* 1896, **4**, 488.

In the volumetric determination of invert sugar by means of Fehling's solution, the cuprous oxide often remains yellow, and the liquid does not clear, so that the exact final point is difficult of observation. The author finds that this is due to the acidity of the solution. It may be avoided by making alkaline with concentrated potash, before adding the Fehling's solution. In the case of wines it is not possible to make the liquid alkaline, because of the resulting precipitation of phosphates; the feeble acidity usually met with in wines is, however, no obstacle; therefore the following process is recommended. Solutions of hydrochloric acid and potash are prepared exactly equivalent to one another, 50 c.c. of the wine are inverted by 2.5 c.c. of acid, and, after cooling, 2.5 c.c. of potash are added, and the liquid made up to 55 c.c.—A. C. W.

*Sugar Solutions, On the Clarification of, for Analysis.* K. C. Neumann. *Bull. de l'Assoc. des Chim. de Sucr. et de Dist.* 1896, **14**, 524—526. (From Oest. ung. Zeits.)

The author examines the effect on polarisations, of the addition of alum. His results show that an immoderate excess of alum affects the polarisation, and has an injurious action on the colour of sugar solutions; but that 1 to 2 c.c. of a saturated solution of alum added with 1 to 2 c.c. of basic acetate of lead, as adopted by the Austro-Hungarian chemists in 1890, has absolutely no injurious effect, but gives an absolutely clear solution.—L. J. de W.

*Starch, Hydrolysis of, by Acids; An Analytical Investigation of.* G. W. Rolfe and G. Defren. *J. Amer. Chem. Soc.* 1896, **18**, 869—900.

The authors have carried out investigations to determine whether there is any simple constant relation between the optical rotation and the cupric reducing power of acid hydrolysed starch products; also whether there are any laws that affect the three simple bodies, assumed to be formed, and determined by the usual methods of analysis.

One hundred grms. of a commercial starch of good quality was mixed with a litre of water containing the acid, placed in an autoclave, and when the contents had acquired constant temperature, portions of 50 to 75 c.c. were withdrawn at different stages of the conversion, and shaken with a few grms. of marble dust. Two drops of decinormal sodium hydroxide were then added, and the mixture cooled and filtered. This method of neutralisation gave clear filtrates;

low converted products, however, required to be treated with alumina before filtering. The specific gravity of the sample was estimated by a Westphal balance corrected to a temperature of 15.5°C.; the factor 3.96 being employed to calculate the total solids; the specific rotatory power was determined, also the cupric reducing power, by O'Sullivan's method. The authors have studied the action of acids on starch under varying conditions, and their results show that the cupric reducing power of the total product bears a constant relation to the specific rotatory power, so that the one being known, the other may be calculated. From the curves plotted by taking the values of maltose, dextrin, and dextrose, they have constructed a table, calculated on the factor 3.86, giving the values within one-tenth per cent. of maltose, dextrose, and dextrin, for successive stages of acid hydrolysis represented by each degree of rotation between 195° and 53.5°. From the examination of some commercial glucoses it is concluded that: (1) in any homogeneous acid converted starch product, irrespective of the conditions of hydrolysis, the specific rotatory power always represents the same chemical composition; (2) that only three simple carbohydrates, possible in molecular aggregates (not considering the small amount of reversion products), exist in the solution of a starch product hydrolysed by acids.

A table is appended, from which the specific rotatory power may be quickly calculated; it is recommended as being useful for the control of the acid conversion. Curves are added showing the influence of temperature, of  $\frac{1}{10}$ N sulphurous-,  $\frac{1}{10}$ N acetic-,  $\frac{1}{10}$ N oxalic-,  $\frac{1}{10}$ N sulphuric-, and hydrochloric acid; of the concentration or amount of acid used; and of the relative curves due to temperature.

—J. L. B.

*Wine, Determination of Lactic and Succinic Acids in.* J. A. Muller. *Bull. Soc. Chim.* 1896, **15**, [23], 1203—1206.

In the determination of lactic and succinic acids in wine, these two acids may be separated by titration with barium hydrate and treatment of the resulting barium salts with alcohol, in which the barium lactate alone dissolves. From the barium found in the solution and in the residue, the amounts of each of the two acids may be calculated. The results found, however, do not agree with the quantities originally present in the wine; and, as the result of three experiments, the mean ratio of lactic acid present to that found is as 1.5:1, whilst, in the case of succinic acid, the mean ratio is 1.2:1. With regard to the lactic acid, the difference is attributed mainly to the volatilisation of the acid, which is found to take place (see following abstract) during the desiccation *in vacuo* of the residue from the evaporation of the wine.—A. K. M.

*Lactic Acid and its Anhydrides, Volatilisation of, at the Ordinary Temperature, and the Volatilisation of Lactic Acid by Steam.* J. A. Muller. *Bull. Soc. Chim.* 1896, **15**, [23], 1206—1210.

When a solution of lactic acid is evaporated over sulphuric acid and the residue exposed for some days in a vacuum, an appreciable quantity is lost by volatilisation. Thus, in one experiment, 0.1280 grm. of lactic acid lost 0.0112 grm. in four days, and, in a second experiment, the loss was 0.0217 grm. in 11 days (the amount of acid in each case being determined by hot titration). In another series of experiments an ethereal solution of lactic acid was employed; the volume of solution taken contained 0.0941 grm. (determined by hot titration with the help of barium hydrated solution), and, after 18 days' exposure in a vacuum, this lost 0.0162 grm. Lactic anhydride, on the other hand, is almost non-volatile under the same conditions, 0.1511 grm. losing only 0.0028 grm. in 25 days. Lactide is more volatile than the latter. When a solution of lactic acid is distilled, the amount of acid carried over with the aqueous vapour increases with the strength of the solution, but here again the amount volatilised is only small; thus 200 c.c. of solution, containing 9.348 grms. of acid, lost only 0.1583 grm. with 190 c.c. of distillate.

Although lactic acid is thus shown to be only slightly volatile under the conditions described, its volatility is

sufficient to account for the discrepancies occurring in wine analyses made by the method mentioned in the preceding abstract.—A. K. M.

*Acetone, Volumetric Determination of.* E. R. Squibb.  
J. Amer. Chem. Soc. 1896, **18**, 1068—1079.

AFTER fully describing the method of Robineau and Rollin (*Monit. Scient.* 1893, 272; this *Journal*, 1893, 870), the author suggests certain modifications whereby the process may be rendered simpler and more rapid. The following solutions are prepared:—(1) Standard acetone solution containing 1 gram acetone in 100 c.c.; this solution should be kept in a dark glass bottle. (2) Potassium iodide solution prepared by dissolving 250 grams of the salt in one litre of water, and adding 850 c.c. of sodium hydrate solution, 257 grams per litre. (3) Sodium hypochlorite, a suitable strength being that of the "liquor sodæ chloratæ" of the U.S. Pharmacopœia, which contains 2.6 per cent. of available chlorine. To each litre is added 25 c.c. of sodium hyposulphite solution, 257 grams per litre. (4) Starch solution, 0.125 gram of starch is mixed with 5 c.c. of cold water, and then added to 20 c.c. of boiling water and boiled; when cold, 2 grams of sodium bicarbonate are added and dissolved with stirring.

*Titration.*—10 c.c. of the standard acetone solution and 20 c.c. of the alkaline iodide solution are added together and well stirred. The hypochlorite is added from a burette, iodoform being precipitated, and the end of the reaction is indicated by a blue colour being given with starch; the exact details of working are as given in the paper of Robineau and Rollin (reference above). The hypochlorite equivalent of 0.1 gram of acetone is thus found, and from this the percentage of acetone in a solution of unknown strength can be rapidly estimated; for this purpose from 0.1 to 0.4 c.c. of the solution should be taken, according to its approximate strength. This is weighed, diluted, and titrated as above. Since the hypochlorite solution diminishes in strength on keeping, it should be frequently standardised by means of the standard acetone solution.

The author confirms the statement of Robineau and Rollin, that the presence of ethyl alcohol does not affect the titration of acetone by this method.—R. B. B.

*Sandal-wood Oil.* A. J. Hendrix. J. Pharm. Chim. 1896, **4**, 199.

A GOOD sample, according to Cripps, should be colourless or slightly yellow, have a thick consistence, a strongly aromatic odour, a piquant, spicy taste, and a neutral or slightly acid reaction. Schimmel and Umney agree that the density should not be less than 0.975 at 15°, and that the oil should dissolve in 5 parts of alcohol of 70 per cent. by volume; this test detects adulteration with 5 per cent. of the following essences: cedar-wood, West Indian sandal-wood oil, santal-macassar, turpentine, copaiba, and castor oil. Pure sandal-wood oil which is old, or has been badly preserved, may not, however, give a clear solution. The author proposes the following test, suitable for use with small quantities:—Weigh into a 10-c.c. flask 2 grams of a solution of 3 parts of crystallised phenol in 1 part of alcohol, add 0.5 gram of the oil, and mix perfectly. Add 0.5 gram of concentrated hydrochloric acid without shaking. At the intersection of the liquids there is formed with pure sandal-wood oil a yellow coloration, changing in a few minutes to a bright red. With essence of balsam of copaiba, the upper liquid becomes mauve-coloured after a few minutes. With oil of cedar-wood, the upper liquid becomes cloudy, and a brownish coloration is developed at the intersection. East Indian sandal-wood oil is levo-rotatory,  $-16^{\circ}$  to  $-20^{\circ}$  (Schimmel and Umney), whilst oil of cedar is much more levo-rotatory, and sandal-wood oils of the West Indies and Australia are dextro-rotatory.

Perry recommends determination of the alcohol, santalol, by boiling with acetic anhydride with a little sodium acetate for 1½ hours, washing the acetate, drying, and saponifying. A good oil contains at least 90 per cent. of santalol; cedar oil contains only 15 per cent., and balsam of copaiba 7 per cent. of alcohol.—A. C. W.

*Tartar Estimation, A Modification of Goldenberg's Method for.* M. Zecchin. *Stat. Sper. Ag. Ital.* **28**, 788; and *Analyst*, 1896, **21**, 333.

WEIGH out 3.75 grams of the finely powdered substance, and dissolve in hydrochloric acid on the water-bath; after 10—15 mins. make up to 100 c.c. and filter off 50 c.c. Add solid potassium carbonate in very slight excess, boil for some minutes, and make up to 100 c.c. Filter off 20 c.c., add 5 c.c. of glacial acetic acid and 100 c.c. of a mixture of equal parts of alcohol and ether, allowing the solution to stand in a closed flask for four or five hours. Filter, and wash the precipitate with the ether-alcohol mixture till neutral, dissolve in boiling water, and titrate with  $\frac{1}{100}$  N alkali, using phenolphthalein as indicator. Each c.c. indicates 2 per cent. of tartaric acid. (See *Analyst*, **21**, 76.)—A. S.

## XXIV.—SCIENTIFIC & TECHNICAL NOTES.

*Chrysoidine, Behaviour of, towards Cholera Bacilli.* A. Blachstein. *Münchener Med. Wochenschr.* 1896, **43**, 1067.

CHRYSOIDINE quantitatively precipitates cholera bacilli from solutions in which they are held in suspension, the precipitate being largely flocculent in character; it thus behaves like "cholera-immun-serum," and may be regarded as an artificial cholera-agglutinant. Other azo-dyes, even those so nearly related to chrysoidine as its sulphonic acid or Vesuvine, do not possess this property; and the reaction appears to be specific for the cholera bacilli, for none of the other similar vibrios examined gave a like result. It is, however, a good disinfectant for the whole group, occupying in this respect a position half-way between mercuric chloride and phenol. It is not in the least poisonous, a property which is in favour of its finding practical use. Tried as a remedy for cholera, it has given negative results, but it may yet prove to have some prophylactic value. It could certainly be used for the disinfection of large volumes of water, or of the mouth, œsophagus, or stomach. In the dissolved form, it was found not to penetrate to the intestinal canal, but to be separated by the kidneys.—W. G. M.

*Cotton-Wool, Absence of Pentose Derivatives in.* H. Surinagar and B. Toliens. *Zeits. f. angew. Chem.* 1897, **4**.

TO test the statement by Link and Voswinkel (*Pharm. Centr.* 1893, 253), that wood gum (a derivative of pentose) is formed in the hydrolysis of cotton, pure cotton wool was heated to the temperature of boiling water, with 4 per cent. sulphuric acid, for eight hours. After removal of the acid, by means of calcium carbonate, a small quantity of a syrup was obtained from the liquid. The reactions of this syrup showed that in all probability it consisted mainly of dextrose. Purified cotton-wool, therefore, contains practically no wood gum, the small quantity of sugar obtained, belonging to the glucose series, and being probably formed by the hydrolysis of the cellulose itself.—T. E.

*Antimonio-tungstates.* L. A. Hallopeau. *Comptes rend.* 1896, **123**, [24], 1065—1068.

HYDRATED antimonious acid can combine with tungstic acid to form antimonio-tungstic compounds analogous to phospho-tungstic and arsenio-tungstic compounds. Details of methods of preparation are given.—J. T. D.

*Metallic Sulphides [Sulphides of As, Sb, and Sn], The Action of Acid Vapours on.* J. Kelley, jun., and E. F. Smith. J. Amer. Chem. Soc. 1896, **18**, 1096—1098.

ARSENIC and antimony trisulphides, and also stannic sulphide, are completely volatilised when exposed to the action of hydrochloric or hydrobromic acid gas. The action commences in the cold with formation of a liquid that passes out of the containing vessel upon the application of a very gentle heat.

If stannous sulphide be subjected to the action of hydrochloric acid gas in the cold, it is completely converted into the chloride without volatilisation; but it is not possible to separate stannous from stannic sulphide by this means, since the heat required to completely volatilise the latter

would also cause partial volatilisation of the stannous chloride.—R. B. H.

*Platinum, The Action of Phosphorus on.* A. Granger. Comptes rend. 1896, 123, 1284.

It is well known that platinum-crucibles in which substances capable of liberating phosphorus are heated, are liable to be pierced by the formation of a fusible phosphide; but, nevertheless, it has been found difficult to obtain the phosphides of definite composition. Two porcelain boats, one containing platinum and the other red phosphorus, were gently heated in a glass tube through which carbon dioxide was passed, the temperature being slowly raised until most, but not all, of the phosphorus was distilled. The phosphide thus obtained was dark grey, and friable, but showed no definite crystals. With platinum wire or foil, the attack does not begin below a red heat; and at a still higher temperature phosphides poor in phosphorus are obtained, approaching in constitution to  $Pt_3P$ , whilst at a "red white" heat the phosphide retains only 4 per cent. of phosphorus. With spongy platinum the action begins below a red heat, and a biphosphide is formed. Contrary to Schrötter's statement, the author did not find the compound to be completely soluble in aqua regia, the dissolved portion exactly corresponding to  $Pt_3P_2$ .—E. S.

*Yeast, Consumption of [Organic] Acids by.* J. Schukow. Centralbl. Bakteriöl. 1896, 2, 601.

The experiments were conducted in flasks, which were weighed from time to time, in order to trace the progress of fermentation; and at stated intervals measured samples were withdrawn for titration by  $\frac{1}{10}$  N caustic soda solution. Various nutrient solutions, mixed with different organic acids, were thus inoculated with pure cultures of yeast. Of the four acids named, citric acid was the most readily consumed, then malic acid, much less tartaric, and only to a slight extent succinic acid. Under like circumstances, different cultures of yeast give different quantitative results with each acid. Usually the consumption is greater when the yeast is well provided with nitrogenous food.—W. G. M.

*Soluble Oxidising Ferments and Drugs.* E. Bourquelot. J. Pharm. Chim. 1896, 4, 481.

VARIOUS aromatic phenols and amines may be distinguished by means of oxidising ferments (from mushrooms) (see Bourquelot, this Journal, 1896, 683, 748; Bertrand, 1896, 561). Guaiac carbonate is not directly oxidised by the ferment, but if the solution be warmed with a few drops of dilute caustic soda, and then slightly acidified by acetic acid, the yellow coloration characteristic of guaiacol is produced on addition of the ferment. Of the natural alkaloids, morphine is oxidised by the ferment in dilute alcoholic solution, giving a yellowish-white precipitate. In one experiment, using 0.3 grm. of alkaloid, a diminution of 19 c.c. in the volume of air contained in the vessel was noticed.

A weak alcoholic solution of the gum resin of asafetida gives at first a rose coloration, then a yellow precipitate; galbanum and gum ammoniac, brownish precipitates; podophyllum resin in dilute alcohol, a brownish-yellow coloration; the creosote of pharmacy, since it contains both cresol and guaiacol, a reddish-yellow precipitate; wood-tar water, a yellowish precipitate; coal-tar water, a brown, almost black, coloration.

Many vegetable substances, when fresh, contain oxidising ferments which are destroyed on drying; the dry leaves of chicory, the dry roots of dandelion, chicory, marsh-mallow, &c., will, however, contain a ferment which can be extracted by trituration with sand and water. Gum-arabic and the gum of the apricot tree also contain an oxidising ferment. The kola nut probably contains a tannin united to caffeine and glucose (kolanine); this compound is decomposed by the oxidising ferment in the kola, the tannin forming a coloured compound. It is only after this oxidation has taken place that caffeine can be extracted by chloroform. The oxidation takes place slowly in the absence of the ferment, rapidly in its presence. This explains the variations in determinations of caffeine (see this Journal, 1896, 670).—A. C. W.

## EDUCATIONAL.

*Chemical Research.* Circular issued by City and Guilds of London Institute.

HIGHER research in chemistry in its relation to manufactures is to be further encouraged by the foundation of one or more Fellowships, tenable at the City and Guilds of London Institute. The Leathersellers' Company is providing the necessary funds, a grant of 150*l.* a year being offered for the purpose. The amount of the grant attached to each Fellowship will be determined by the Executive Committee of the Institute, regard being had as far as practicable to the nature of the research, the time required to complete it, and the merits of the candidate, subject in all things to the approval of the Company. The Fellowships are confined to natural-born British subjects, who have completed a full three years' course of instruction in the Chemical Department of the Central Technical College, or who are otherwise duly qualified in the methods of chemical research in its relation to manufactures. They will be tenable for part of a year or a whole year, and may be renewed for a second or third year, all researches by Fellows being carried out at the Central Technical College. Applications for Fellowships must be addressed to the Honorary Secretary of the Institute, Gresham College, E.C.

*The Teaching of Chemistry.* The Times, Feb. 5, 1897.

ABOUT two years ago *The Times* published a letter by Prof. Armstrong, in which attention was directed to the very unsatisfactory character of the instruction in chemistry that was being given, under the auspices of the Technical Education Board of the London County Council, to science teachers in schools. The great danger they incurred in setting such an example was dwelt on, and the more desirable direction for the Board to follow was pointed out. The letter had some effect, for after a time a sub-committee was appointed to consider the teaching of chemistry in schools and evening classes. This committee consisted of six members of the Board, besides Dr. Russell, F.R.S. (chairman), Dr. Ludwig Mond, F.R.S., and Prof. Ramsay, F.R.S.—three chemists well known not only in the scientific world—and Mr. C. M. Stuart, head master of St. Dunstan's College, Catford. As Sir Philip Magnus and Prof. James Stuart, both members of the Board, were on the committee, and Dr. Garnett, the Secretary to the Board, and also Dr. Kimmins acted as its advisers, there was no lack of educational experience; indeed, the committee was an exceptionally strong one. A report signed by the chairman and secretary of the Technical Education Board, embodying the recommendations of this sub-committee, has just been issued. This report, it may safely be said, is destined to mark an era in the "technical" education movement in this country, both because of the example its issue sets to county councils generally, and more particularly on account of the recommendations which are put forward in it. Of all the work hitherto done by the Board, probably none is of more fundamental importance, as it will give help in a direction in which help has long been sorely needed and of which there was little prospect or hope, and, coming from such a source, the report is a peculiarly valuable contribution to the inquiry which is now being actively prosecuted into methods of education with the object of ascertaining which are the most likely to promote technical progress.

Extracts from the evidence taken by the committee are given in the report. That of Dr. Mond is of the highest value. He gave the opinion that the teaching of technological chemistry in schools or similar institutions was of no value whatever either for chemical industries or for the pupils. He advised that the Board should confine its energies to the teaching of scientific chemistry as an educational discipline, and that special knowledge in chemistry could only be imparted in institutions of university rank, where the student was bound to devote years to thorough study under the guidance of eminent teachers.

Dr. Messel, another German, who is an English manufacturer and also a highly-trained scientific chemist, gave similar evidence. According to this witness, chemical industry on the Continent is ahead of that in this country, because science is accorded a consulting and deliberating

voice abroad, and because there are mostly found at the head of affairs people who possess a thorough scientific education. Only a complete training is of value for industrial purposes. To keep abreast of other nations English industries require the services of thoroughly trained men; it must be realised, this witness said, that what creates and maintains the industry of a country is neither capital nor labour, but brains.

Owing to their intimate knowledge of the conditions which prevail in German as well as in English works, the opinions of these two witnesses are invaluable. But Mr. Howard and others expressed similar views. Much evidence was taken by the Committee as to the character of the training most suitable for different classes of students, and it is on this subject that they make most important recommendations.

They begin their report with the statement:—"We are of opinion that the teaching of chemistry in schools should be solely of an educational nature, and should have no reference to practical (*i.e.*, technical) application." Nothing could be clearer, more emphatic, or more in accordance with the opinion of all who have real knowledge of the subject. Among the general conclusions arrived at, the following deserve special notice, as they enunciate educational doctrines of startling boldness and breadth in comparison with those now prevailing:—

That as a branch of elementary education chemistry, when properly taught, is a most effective means of cultivating power of observation and accuracy of thought, and consequently it should form a part of school work on account of its educational value and not because the facts it deals with may be of commercial importance. Further, we are of opinion that even this elementary teaching of chemistry should be largely carried out by means of practical work, the students being induced to form deductions from their own work and to solve problems by actual experiment.

That in carrying out the chemical teaching special attention should at the same time be paid to the writing, spelling, and clearness of expression in all notes and description of experiments, so that the teaching of these subjects may be to a considerable extent interwoven with the chemical teaching.

We are also of opinion that the Board may do great good by enabling scholars who have shown special aptitude for the study of elementary science, to continue such studies. We are, however, strongly of opinion that such a selection cannot be satisfactorily made by any ordinary system of examination, but could be made by the head master or some other officer of the school, who has personal knowledge of the work which has been done during the whole of the scholar's school career. We are much impressed by the evils arising from the too frequent examination of young students.

Passing from the teaching of chemistry simply as an element of education to the teaching of it with the special object of fitting a student for taking an important position in a chemical manufactory, we are convinced that the course of study must extend over several years and be of university standard; that the chemist in a manufactory, if he is to be efficient and able not only to cope with occasional and accidental difficulties, but also able to improve and extend the manufacture, must be a man who has not only had a thorough training in scientific chemistry but has also had experience in original research. Training of this character should be, and in fact is, given at certain colleges in this country, and should be attainable by those who can show that they have special aptitude and inclination for this kind of work. We desire to emphasize most strongly this need of the highest chemical instruction for the technological chemist, and we believe that the employment of men thus educated in the chemical works of this country would prove of great advantage, not only to the manufacturer, but also to the country in general.

If the conclusions of the committee are in any way accepted and carried out within the jurisdiction of the Council, there is little doubt that nothing short of a revolution will be effected, and that science will at last become of some use as an element in our system of education. The

Technical Education Board have now a great opportunity, but no light task, and if they are wise their first step will be to appoint an educational council to act as their advisers from among those who are acknowledged leaders in such work in London. Teachers must be trained—for there are very few available at present; and examinations must, as far as possible, be put to an end to. It is too terrible that 81.6 per cent.—so the report informs us—of the students attending evening classes at a number of the chief polytechnics and institutes in the London district should be preparing for the examinations of the Science and Art Department, knowing as we do the worthlessness of these as tests of ability to do anything rational or useful. It is to be hoped that the Board will take action to encourage the following of an example such as that set by the Finsbury Technical College, which alone of all the institutions where evening classes are held pays no heed to examinations. And, having now formally entered on the crusade against examinations, the Board are bound to look at home and see that those they impose are carried out as efficiently as possible, and so as to do the *minimum* of harm; for they cannot do good, necessary as they may be.

Among the recommendations made under the head of instruction of university standard during the day, there is one which is of extreme importance at the present juncture in view of the possible establishment of a teaching university in London—*viz.*, the following:—"We cannot refrain from observing that the higher technical instruction in chemistry in London would probably be rendered more efficient and accessible if the work of the several institutions in this subject were better co-ordinated.

The Board are to be highly congratulated on the statesmanlike attitude assumed throughout by their sub-committee, and it is to be hoped that they will spare no effort to carry out the recommendations of the report which they have so wisely accepted.

## Trade Report.

### OFFICIAL NOTICE.

#### CARBIDE OF CALCIUM.

In consequence of the growing importance of carbide of calcium and the fact that the mere contact of moisture with this material causes a dangerous evolution of the highly inflammable gas known as acetylene, the Home Secretary has caused inquiries to be made into the subject, with the result that an Order in Council has to-day been made under the 14th section of the Petroleum Act, 1871, bringing carbide of calcium within the operation of that Act.

Accordingly, from the date on which such Order comes into force, *viz.*, 1st April 1897, it will be unlawful to keep carbide of calcium except in virtue of a license to be obtained from the local authority under the Petroleum Act.

Any local authority to whom application may be made for a license to keep carbide of calcium can, if it so desires, obtain, on application to the Home Office, a memorandum showing the character of the risks to be guarded against, and containing suggestions as to the nature of the precautions likely to be most effectual for securing safety.

Whitehall,

26th February 1897.

### PROPOSED LEGISLATION.

#### STEAM ENGINES AND BOILERS (PERSONS IN CHARGE).

##### *A Bill to grant Certificates to Persons in Charge of Steam Engines and Boilers.*

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. This Act may be cited as the Steam Engines and Boilers Act, 1897.

2. This Act shall come into operation on the 1st day of January 1898, which date is in this Act referred to as the commencement of this Act.

3. In this Act—

The term "boiler" means any closed vessel used for generating steam, or for heating water, or for heating

other liquids, or into which steam is admitted for heating, steaming, boiling, or other similar purposes; The term "engine" means any engine used in the production of motive power, and worked by steam from a boiler;

The term "horse-power" means nominal horse-power.

4. This Act does not apply to any boiler or engine used exclusively for domestic, agricultural, or farming purposes, or to any boiler or engine used in the service of Her Majesty, or to any boiler or engine used by a railway company, or to any boiler or engine used on board a steamship having a certificate from the Board of Trade, or to any road traction engine or steam roller.

5. After the commencement of this Act it shall not be lawful for any person to take the charge or control of, or to employ another person to take the charge or control of, any boiler or engine to which this Act applies, unless the person so taking charge or control is qualified as required by this Act.

6. The qualifications required by this Act are as follows:—

(i.) A person taking charge or control of any boiler or engine to which this Act applies, of five horse-power or upwards, or of any engine to which this Act applies, used for winding workmen or minerals up or down the shaft of a mine, must hold a first-class certificate or a special certificate of service under this Act.

(ii.) A person taking charge or control of any other boiler or engine to which this Act applies must be the holder either of such a certificate as aforesaid, or of a second-class certificate under this Act.

Provided that in the case of any works or mine where there are more than one boiler or engine to which this Act applies, it shall be sufficient if they are under the constant supervision of one person possessing the qualification required in respect of them by this Act; so, however, that no one person shall undertake the supervision of a greater number of boilers or engines, or of boilers or engines situate at a greater distance from one another, than may be prescribed by any regulations of the Board of Trade for the time being in force, and the Board may make such regulations accordingly.

7. Any person who takes charge or control (save in case of a sudden emergency) of a boiler or engine to which this Act applies, without possessing the qualification required by this Act, shall be liable to a fine not exceeding for the first offence 40s., and for the second or any subsequent offence 10l.

Any person who employs another person to take charge or control (save in case of a sudden emergency) of a boiler or engine to which this Act applies, without possessing the qualification required by this Act, shall be liable to a fine not exceeding for the first offence 10l., and for the second or any subsequent offence 50l.

8. A person who has passed an examination held under this Act shall be entitled to receive a first-class certificate from a Secretary of State.

A person who within three months before or after the commencement of this Act produces to a Secretary of State satisfactory evidence that for not less than 12 months before the commencement of this Act he has within the previous five years had the practical charge or control of a boiler or engine of five horse-power or upwards shall be entitled to receive from a Secretary of State a special certificate of service, which for the purposes of this Act shall be equivalent to a first-class certificate.

A person who produces to a Secretary of State testimonials from at least two persons, which satisfy the Secretary of State that he is, in point of character, knowledge, physical ability, and experience, fit to receive a second-class certificate under this Act, shall, on so satisfying the Secretary of State, be entitled to receive a second-class certificate.

9. An applicant for a certificate under this Act shall pay to a Secretary of State such fee as may be from time to time prescribed by a Secretary of State, not exceeding, in the case of a first-class certificate, the sum of 5s., and in the case of any other certificate, 2s. 6d.

10.—(1.) All certificates shall be made in duplicate, one part to be delivered to the person entitled to the certificate, and one to be preserved.

(2.) Such last-mentioned part of the certificate shall be preserved, and a record of certificates and of the suspending, cancelling, or altering of the certificates, and of any other matter affecting them, shall be kept in such manner as a Secretary of State directs.

(3.) Any such certificate and any record under this section shall be admissible in evidence.

11. If the holder of a certificate under this Act proves to the satisfaction of a Secretary of State that he has, without fault on his part, lost or been deprived of a certificate already granted to him, the Secretary of State shall, and in any other case may, on payment of such fee (if any) as he directs, cause a copy of the certificate to which by the record kept in pursuance of this Act he appears to be entitled, to be certified by the person directed to keep the record, and to be delivered to him; and a copy purporting to be so certified shall have all the effect of the original.

12. If any person—

(a) forges or fraudulently alters, or assists in forging or fraudulently altering, or procures to be forged or fraudulently altered, any certificate, or an official copy of any such certificate; or

(b) makes, assists in making, or procures to be made, any false representation for the purpose of procuring, either for himself or for any other person, a certificate; or

(c) fraudulently uses a certificate or copy of a certificate which has been forged, altered, cancelled, or suspended, or to which he is not entitled; or

(d) fraudulently lends his certificate, or allows it to be used by any other person;

that person shall in respect of each offence be guilty of a misdemeanour.

13. A Secretary of State, on good cause shown, may cancel or suspend any certificate granted under this Act, and may at any time, on appeal being made to him by the person whose certificate has been suspended, and on production of evidence in support of his appeal, restore any cancelled or suspended certificate, with or without a statement to that effect appended thereto.

14. A first or second class certificate granted to an engineer under the Merchant Shipping Act, 1894, shall for the purposes of this Act be deemed to be equivalent to a first-class certificate granted under this Act.

15. In the year commencing with the 1st day of January 1898, and in every succeeding year, a Secretary of State shall cause to be held, as often as he deems necessary, examinations for the purpose of testing the qualifications of candidates for first-class certificates under this Act.

The Secretary of State shall have the entire management and control of all such examinations, and shall have power from time to time to make regulations with respect to all or any of the following matters; (that is to say.)

(a.) With respect to the subjects for and the mode of conducting the examination of candidates; and

(b.) With respect to the times and places of examinations, and the notices of examinations; and

(c.) With respect to the evidence to be given by applicants of physical ability, experience, and character; and

(d.) With respect to the appointment and removal of examiners, and with respect to the remuneration by fees or otherwise of the examiners so appointed; and

(e.) With respect to any other matter or thing as to which a Secretary of State thinks it expedient to make regulations for the purpose of carrying this section into execution.

Any regulation made under the authority of this section may be altered or revoked by a subsequent regulation.

16. Any offence against this Act may be prosecuted, and any fine in respect thereof may be recovered, in manner provided by the Summary Jurisdiction Acts.

17. The expenses of a Secretary of State in carrying out the provisions of this Act shall be defrayed out of moneys provided by Parliament.

## EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

### THE ANGLO-SICILIAN SULPHUR COMPANY.

*Board of Trade J., Feb. 206.*

A despatch from Her Majesty's Ambassador at Madrid encloses extracts from the "Italic," which states that the Anglo-Sicilian Sulphur Company has been successful in reviving the declining sulphur industry of Sicily.

The amount of sulphur exported during the months of October and November last from mines which have given in their adhesion to the Society was 60,820,046 kilos.—or, with the other mines, a total of 77,318,795 kilos.

The movement for the month of October 1896 was 43,000 tons, as compared with 22,300 tons for October 1895. The demand from abroad, especially from France and the United States, has been very remarkable.

## GENERAL TRADE NOTES.

### PHOSPHATES IN THE UNITED STATES.

*Eng. and Mining J., Jan. 30, 1897, 199.*

The Southern phosphate miners did not have a prosperous year in 1896, and there was a large decrease in production. The figures as collected by the *American Fertiliser* show a movement for the year as follows, in tons:—

	1895.	1896.		
	Total.	Foreign.	Domestic.	Total.
South Carolina...	515,724	82,260	192,800	275,000
Florida .....	550,356	395,171	103,894	499,065
Tennessee .....	15,329	..	42,911	12,911
North Carolina...	7,500	..	7,418	7,418
Total ...	1,098,519	477,431	347,025	824,454

The total decrease from 1895 was therefore 274,065 tons, or 25 per cent. The South Carolina mines showed the greatest decrease—about 46 per cent.—the reduction in Florida being comparatively slight. The new mines in Tennessee did not add anything to the total for the year, though their shipments will probably be felt in 1897.

A good reason for the decrease in shipments is found in the low prices obtained. Phosphate rock, 58 to 60 per cent., sold in Charleston from 3.25 dol., per ton down to 3 dol., while river rock sold down to 2.85 dol., the closing prices being the lowest of the year. The foreign demand continued to decrease, owing to the competition of the Algerian phosphates and the growing use of basic slag as a source of phosphoric acid; while there was hardly any increase in the domestic demand, to make up for the diminished exports. At the prices noted there can be very little, if any, profit in mining phosphate.

### CHROMIC IRON, WITH REFERENCE TO ITS OCCURRENCE IN CANADA.

W. Glenn. *From 17th Annual Report of the United States Geological Survey, 1895-6.*

Chromite, nominally  $\text{FeO} \cdot \text{Cr}_2\text{O}_3$  with 67.89 per cent.  $\text{Cr}_2\text{O}_3$ , usually has some of each constituent metal replaced by  $\text{Al}_2\text{O}_3$ ,  $\text{MgO}$ ,  $\text{CaO}$ , and  $\text{SiO}_2$ , so that the greater proportion of chrome ore in the market contains 40—46 per cent.  $\text{Cr}_2\text{O}_3$ ; the richest shipment in the experience of the author having averaged 54 per cent.  $\text{Cr}_2\text{O}_3$ . The following are typical analyses of chrome ore in bulk:—

	1.	2.	3.
	Per Cent.	Per Cent.	Per Cent.
$\text{SiO}_2$ .....	7.00	5.22	6.44
$\text{Cr}_2\text{O}_3$ .....	39.15	51.03	53.07
$\text{FeO}$ .....	27.12	13.06	15.27
$\text{MgO}$ .....	16.11	16.32	16.08
$\text{CaO}$ .....	3.41	2.91	1.20
$\text{Al}_2\text{O}_3$ .....	7.00	12.16	8.01

Of these, No. 1 is regarded as a very poor ore, and as containing unusually little  $\text{Al}_2\text{O}_3$ , No. 2 is a rich, and No. 3, a very rich ore. The Canadian ores are hard and tough, with abundance of stones of large size, which bear transport and handling well; so that in this respect they are in marked contrast to the Asiatic ores, which are friable and contain many small lumps and crushed material, and especially so to one Turkish ore, that is yellowish-brown in colour, and so friable that it is generally delivered in the form of fine gravel or sand. Chromite occurs in serpentine, and the only commercially valuable chrome ore known to exist in Canada is found in the great serpentine field in the Coleraine district, 2,837 tons of the ore were shipped from the township of Coleraine in 1895, of which 2,342 tons were consigned to the United States, 441 tons to Great Britain, and 54 tons to Nova Scotia. Besides the above, 1,200 tons were lying at the mines or on the railway. Most of the ore shipped was of the highest quality and was required for the chemical works of Baltimore and Philadelphia. The ore employed in metallurgy may be of inferior grade, and most of the ore sent to England was of the third quality.—W. G. M.

### IRON ORE IN GERMANY, PRODUCTION OF.

*J. Soc. of Arts, 1897, 45, 157—158.*

The total output of iron-ore in the German Customs Union in 1894 was 12,392,065 tons, of this Germany produced 8,433,784 tons, and Luxembourg 3,958,281. About the same amount was smelted, for imports and exports figure nearly alike—2,600,000 tons. From Spain came about 700,000 tons, from Sweden nearly 600,000, and the rest from Algeria, Elba, and Greece—all through the Dutch ports, while about 130,000 tons came from Holland and Belgium.

The production in Upper Silesia has fallen in two years from 723,000 tons to 618,000, and will not last many years, and in Saxony and Württemberg it has practically ceased. In Bavaria and Thuringia a few mines yield about 220,000 tons; in Hanover the aggregate output is about 1,000,000 tons; in Westphalia 200,000 tons; in the Siegerland 1,500,000 tons; and in the Hild and Lahn districts 1,000,000 tons. The Lorraine and Luxembourg districts are much more important. In Luxembourg the output has risen from 911,000 tons in 1870 to 2,960,000 tons in 1894, while in Lorraine the figures are:—1872, 677,000; 1880, 996,000; 1894, 3,922,000 tons. The Luxembourg ore, at the present rates of consumption, will last 135 years for the home consumption and 56 years for export, while the Lorraine beds are estimated to last 800 years.

The German freights, in spite of competition between rail and water, are much higher than those of France and Belgium: 1.96 pfennige per ton of ore per kilo., against about 1.2 pfennige.—J. T. D.

### SPIRIT FOR TECHNICAL PURPOSES, ACTIVITY OF THE GERMAN DISTILLERS' ASSOCIATION FOR THE PROMOTION OF THE EMPLOYMENT OF.

*Dalbrück. Zeits. f. Spiritusind. 1896, 19, 409—410.*

The printing of a statement made by Posadowsky in the Reichstag having given rise to some misunderstanding with regard to the activity of the German Distillers' Association, the writer gives the following particulars:—The Association has actively assisted in developing the employment of spirit for technical purposes, the amount of duty-free spirit used having increased from 38.7 million litres in 1887-88 to 71.2 millions in 1894-95. Application was made to the Secretary of the Imperial Treasury for funds to establish an experimental institution for investigation in the following subjects:—(1) Incandescent spirit lamp; (2) Apparatus for heating with spirit; (3) Spirit motors; (4) Manufacture of alcohol and vinegar; and (5) Alcoholic preparations, jacks, and varnishes. The cost of fitting up such an establishment was estimated at 15,000 marks, and the yearly expenditure at 14,000 marks. The amount granted by the Secretary of the Treasury was 10,000 marks, and with the help of this sum the Association (a) published a collective account of all the technical literature bearing upon the incandescent spirit lamp, (b) offered prizes for

the construction of an incandescent spirit lamp with an illuminating power equal to that of the ordinary petroleum lamps. Twenty lamps were tested, and the best of these gave the following results:—

	Intensity of Light, in Candles.	Cost of Spirit per Hour, in Pfennige.
Incandescent spirit lamp ...	22½ 12½	1½ 1½
		Cost of Petroleum, per Hour.
Large petroleum lamp .....	24½	2½
Small petroleum lamp .....	11½	0½

The question is therefore solved for the well-to-do public. (c) The Association has brought about a reduction in the price of burning spirit by getting the licence removed, the cost of spirit being reduced in many places to 25 pfennige (about 3d.) or less per litre. The employment of spirit for heating and cooking purposes is also being developed, and the engineer of the Association is likewise engaged on the motor question. An experimental station for the alcohol and vinegar industry was to be opened on Jan. 1, 1897.

—A. K. M.

### BOARD OF TRADE RETURNS.

#### SUMMARY OF IMPORTS.

Ivory.....	794	811	40,062	34,464
Manure:—				
Guano..... Tons	870	1,510	3,080	16,755
Bones.....	10,713	7,816	43,157	32,536
Nitrate of soda.....	7,864	7,784	60,148	62,142
Phosphate of lime ..	21,634	20,313	44,495	32,644
Paraffin..... Cwt.	67,783	62,679	71,854	60,390
Linon rags..... Tons	1,748	2,848	17,876	26,857
Esparto.....	14,481	19,471	63,239	78,768
Pulp of wood.....	21,170	58,035	115,757	179,663
Rosin..... Cwt.	211,820	276,780	59,001	65,067
Tallow and stearin ..	206,294	189,386	234,301	188,997
Tar..... Barrels	901	555	392	237
Wood:—				
Hewn..... Loads	126,475	147,880	248,871	271,679
Sawn.....	147,747	138,597	339,582	349,486
Staves.....	19,190	7,991	67,178	39,444
Mahogany..... Tons	3,774	3,248	31,795	28,550
Other articles... Value £	..	..	899,428	857,288
Total value .....	..	..	3,189,712	3,239,851

Besides the above, drugs to the value of \$5,511½ were imported as against 60,454½ in January 1896.

EXPORTS OF METALS (OTHER THAN MACHINERY) FOR  
MONTH ENDING 31ST JANUARY.

Articles.	Quantities.		Values.	
	1896.	1897.	1896.	1897.
Brass..... Cwt.	10,621	9,900	£ 41,431	£ 42,664
Copper:—				
Unwrought..... "	31,222	25,675	92,136	63,248
Wrought..... "	11,550	20,205	111,476	63,089
Mixed metal..... "	23,366	19,011	51,021	25,314
Hardware..... Value £	..	..	181,519	181,325
Implement..... "	..	..	117,025	118,058
Iron and steel..... Tons	237,607	292,266	1,716,072	1,804,496
Lead..... "	3,507	5,338	44,368	42,018
Plated wares..... Value £	..	..	30,880	29,733
Telegraph wires..... "	..	..	57,224	62,120
Tim..... Cwt.	10,255	6,869	33,266	21,498
Zinc..... "	19,272	15,181	12,347	11,363
Other articles..... Value £	..	..	70,272	66,252
Total value.....	..	..	2,558,834	2,535,060

EXPORTS OF DRUGS AND CHEMICALS FOR MONTH  
ENDING 31ST JANUARY.

Articles.	Quantities.		Values.	
	1896.	1897.	1896.	1897.
Alkali..... Cwt.	69,467	327,804	£ 111,143	£ 82,480
Bleaching materials..... "	116,479	94,103	42,194	30,565
Chemical manures..... Tons	29,685	32,846	201,025	185,514
Medicines..... Value £	..	..	102,500	83,648
Other articles..... "	..	..	304,857	345,696
Total value.....	..	..	761,850	727,912

EXPORTS OF MISCELLANEOUS ARTICLES FOR MONTH  
ENDING 31ST JANUARY.

Articles.	Quantities.		Values.	
	1896.	1897.	1896.	1897.
Gunpowder..... Lb.	609,800	1,060,960	£ 16,064	£ 23,273
Military stores..... Value £	..	..	158,692	64,997
Candles..... Lb.	2,539,900	1,873,260	40,443	26,622
Caoutchouc..... Value £	..	..	116,711	97,235
Cement..... Tons	20,612	27,645	33,678	44,485
Products of coal Value £	..	..	177,795	157,185
Earthenware..... "	..	..	158,960	111,483
Stoneware..... "	..	..	12,798	13,552
Glass:—				
Plate..... Sq. Ft.	158,613	147,651	8,508	9,391

Bottles..... "	66,809	65,792	31,265	30,855
Other kinds..... "	23,675	15,087	19,247	14,092
Leather:—				
Unwrought..... "	10,880	10,571	105,060	97,457
Wrought..... Value £	..	..	23,491	28,816
Seed oil..... Tons	4,067	4,451	79,755	78,478
Floorecloth..... Sq. Yds.	2,566,800	1,880,060	99,403	80,550
Painters' materials Val. £	..	..	132,390	119,787
Paper..... Cwt.	95,785	73,170	145,114	119,224
Rags..... Tons	3,229	4,708	25,067	22,506
Soap..... Cwt.	71,140	63,762	70,095	59,565
Total value.....	..	..	2,813,685	2,516,777

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

### I.—PLANT, APPARATUS, AND MACHINERY.

#### APPLICATIONS.

1459. J. Cleghorn and T. Wilkinson. Improvements in apparatus for crushing rock-salt, coke, or other substances. Jan. 19.

1494. S. Chatwood and S. R. Chatwood. Improvements in apparatus for superheating steam. Jan. 19.

1580. J. Thomas and L. P. Thomas. Improvements relating to presses suitable for the treatment of oil-cake and other materials. Complete Specification. Jan. 20.

1663. R. Wright. Improvements in apparatus for compressing air and other gases. Jan. 21.

1843. A. J. Boulton.—From H. H. Dikema. Improved method of mixing or separating solid, liquid, or gaseous bodies in solution with or from other bodies, and apparatus therefor. Complete Specification. Jan. 23.

2618. L. Gunn. An improved refrigerating and cooling appliance. Feb. 1.

2876. J. B. Alliot. Improved method and apparatus for evaporating liquids and condensing. Feb. 3.

2877. J. B. Alliot. Improved methods of and apparatus for cooling and evaporating. Feb. 3.

2900. H. Hirzel. An improved column for condensing, absorbing, heating, distilling, and otherwise treating gases and liquids. Complete Specification. Feb. 3.

2927. E. T. Bousfield. Improvements in apparatus for heating or cooling liquids. Feb. 3.

2931. R. G. Brooke. Improvements in apparatus for purifying fluids. Feb. 3.

3027. Sir C. S. Forbes, Bart. Improvements in condensers. Feb. 4.

3219. G. Zschocke. Improvements in hurdles or grids for gas purifiers and cooling, drying, and graduating apparatus. Feb. 6.

3328. D. Halpin, J. B. Alliot, and L. Sterne. Improvements in cooling liquids and apparatus therefor. Feb. 8.

3482. J. B. Alliot. Improved evaporating process and apparatus applicable for concentrating, cooling, and other purposes. Feb. 9.

3483. J. B. Alliot. Improved methods of and apparatus for cooling and evaporating. Feb. 9.

3592. J. E. Campbell. See Class VII.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1896.

1300. C. Polony. See Class II.

2150. R. Cunliffe. Apparatus for drying brewers' refuse and other materials or substances requiring similar treatment. Feb. 3.

3365. H. B. McKenna. Treatment of hydrocarbons for the production of crystalline substances, and apparatus for treating and manufacturing same. Feb. 17.

4208. W. Griffiths and V. C. Read. Apparatus for treating feed water to prevent incrustation in boilers, applicable for treating or purifying water for other purposes. Feb. 17.

5431. S. M. Lillie. Evaporating apparatus. Jan. 27.

6210. S. T. Wellmann and G. H. Wellmann. Apparatus for charging metallurgical and other furnaces. Feb. 17.

9127. M. Donane. Apparatus for producing cold by means of volatile liquids. Feb. 17.

15,488. F. H. Haviland, A. Holloway, J. B. Collier, and W. H. Murch. New or improved furnace. Feb. 10.

20,987. J. von Grubinski. Apparatus for purifying and heating feed water for steam generators. Jan. 27.

20,716. A. Möller, jun. Drying kiln with sinking shelves. Feb. 17.

28,411. S. Straker. Apparatus for evaporating water containing salts and calcareous matter, and in heating furnaces for removing the incrustation from the coils of such evaporating apparatus. Feb. 3.

28,763. J. V. Johnson.—From The Electric Rectifying and Refining Co. See Class XVII.

## 1897.

852. T. B. Lightfoot.—From the Gesellschaft für Linde's Eismaschinen. Apparatus for the production of ice and for cooling liquids by the expansion of compressed air. Feb. 17.

## II.—FUEL, GAS, AND LIGHT.

### APPLICATIONS.

1254. R. J. Moss. An improved apparatus for generating and purifying acetylene gas. Jan. 18.

1370. F. G. Bartlett. An improvement relating to incandescent gas-lighting. Jan. 19.

1398. W. R. Addicks. Improvements in the manufacture of carburetted water-gas and in apparatus therefor. Complete Specification. Jan. 19.

1440. A. J. Boulton.—From H. F. Fuller. Improvements in or relating to apparatus for the generation of gas. Complete Specification. Jan. 19.

1490. G. Baldwin. Improvements in apparatus for the manufacture of acetylene gas. Jan. 19.

1519. A. Sterza. Apparatus for preparing or rendering acetylene gases fit for heating purposes. Complete Specification. Jan. 20.

1653. G. de R. de Sales. Process for the agglomeration of carbides. Complete Specification. Jan. 21.

1776. C. Pond and R. S. Richards. Improvements in the manufacture of calcium carbide and apparatus therefor. Jan. 22.

1777. L. Denayrouze. An improvement in burners for incandescent gas lights. Jan. 22.

1784. W. P. Thompson.—From A. Gobron. Improved portable apparatus for generating and burning acetylene gas. Jan. 22.

1879. A. Trosier. Apparatus for generating acetylene gas and regulating its production. Jan. 23.

1923. S. J. von Romoeki and H. Ascher. Improvements in incandescent gas burners. Jan. 25.

1929. T. Thorp and T. G. Marsh. Improvements in and relating to apparatus for the production of acetylene from calcium carbide. Jan. 25.

1935. W. H. Chambers. Improvements in the manufacture of coke. Jan. 25.

1952. J. C. Mewburn.—From A. M. Scott. Improvements in apparatus for generating gas by the reaction of solid substances with water or other liquid, especially applicable to the generation of acetylene gas by contact of water with metallic carbides. Jan. 25.

2032. T. Lyons, J. Lyons, and J. Pearson. Improvements in acetylene gas store generators. Jan. 26.

2050. C. Kaestner. Burner for use with acetylene gas. Jan. 26.

2065. A. J. Boulton.—From C. Benoit and A. Graviere. Improvements in or relating to apparatus for the production of acetylene gas. Jan. 26.

2071. J. Bowing. Improvements in the process of and apparatus used for coking. Jan. 26.

2113. J. Spurge. Improvements in gas-cleansing apparatus. Jan. 26.

2129. W. L. Wise.—From A. Piatti and Co. Improvements in the manufacture of gas. Jan. 26.

2176. W. J. Engledue. Improvements in or relating to the generation of heat from fuel. Jan. 27.

2194. P. W. von Gehlen. An apparatus for producing and using an incandescent light produced from benzene gas. Complete Specification. Jan. 27.

2260. F. S. Thorn and C. Hoddle. A new and improved acetylene jet for optical lantern use. Jan. 28.

2261. F. S. Thorn and C. Hoddle. A new and improved receptacle for safely storing calcium carbide. Jan. 28.

2262. F. S. Thorn and C. Hoddle. A new and improved lantern-view dissolver for acetylene gas. Jan. 28.

2284. R. F. Carter. Improved apparatus for the production and storage of acetylene gas. Complete Specification. Jan. 28.

2292. G. de R. de Sales. Apparatus for generating and storing acetylene. Complete Specification. Jan. 28.

2337. G. W. B. Crees. Improved means for and method of producing acetylene gas. Jan. 28.

2428. H. R. Bean and H. Ringwood. An improved generator condenser and holder for acetylene and other gases. Jan. 29.

2511. T. Holmes, G. S. Holmes, and R. W. Stewart. An improved process for the production of inflammable gas. Jan. 30.

2551. J. Gilligan. Improvements in mantles for incandescent lighting. Jan. 30.

2554. E. G. Villejean and H. J. J. Frossard. Apparatus for the automatic generation of acetylene gas. Jan. 30.

2574. J. Akroyd and B. Akroyd. (Excelsior) acetylene gas generator. Feb. 1.

2738. P. B. Watson. Apparatus for producing atmospheric gas from liquid hydrocarbons. Feb. 2.

2756. E. A. Javal and G. Cargill. Improvements in apparatus for the production of acetylene gas. Feb. 2.

2863. W. C. Tyler. Improvement relating to apparatus for the production of oxygen from the atmospheric air. Feb. 3.

2894. H. Maxim. An improved method of and apparatus for the production of calcium carbide, applicable also to other purposes. Feb. 3.

2945. T. Thorburn. An improved generator for the manufacture of acetylene gas. Feb. 4.

2976. W. H. Dennis. Acetylene gas lamps and generators. Complete Specification. Feb. 4.

2984. H. Walker. An improved process and apparatus for the production and purification of acetylene gas. Feb. 4.

3013. W. P. Thompson.—From P. P. H. Mace and L. L. H. Gerard. Improvements in apparatus for the production of acetylene gas. Feb. 4.

3029. W. C. Tyler. Improvement in apparatus for the production of oxygen from the atmospheric air. Feb. 4.

3060. J. B. Fenby. Improvements in apparatus for producing acetylene. Feb. 5.

3129. A. Freitag. Improvements relating to the burning of pulverulent fuel and to apparatus therefor. Feb. 5.

3504. J. Wilson. Improvements in and in the manufacture of burners for incandescent gas lighting. Feb. 10.

3539. A. Rose. Improvements in and connected with burners for incandescent gas lights. Feb. 10.

3667. H. A. Kent. Inverted regenerated incandescent gas burners or lights. Feb. 11.

3823. J. P. van der Ploeg. Improvement of the heating system applicable to most different furnaces, ovens, kilns, and other producers of heat by combustion of any combustible. Feb. 12.

3891. J. W. Leadbeater. An improved mode of admixing and preparing petroleum and other matter in compound form with a view to its final use as a combustible. Feb. 13.

3892. J. W. Leadbeater. Improvements in the manufacture of briquettes or blocks of fuel from waste products or otherwise enriched by petroleum compounds. Feb. 13.

3898. E. Richard. Improvements in the manufacture of calcium and other carbides. Feb. 13.

3975. E. L. Browne. An acetylene gas generator. Feb. 13.

3981. A. V. Cristiani and O. Scholzig. Improvements in and connected with apparatus for generating, purifying, cooling, storing, and directly supplying acetylene gas. Feb. 13.

## COMPLETE SPECIFICATIONS ACCEPTED.

1895.

24,088. W. Symcock and G. Gosling. An apparatus for the production and automatic distribution of acetylene gas. Jan. 27.

1896.

1300. C. Polony. A process and furnace installation for continuous process of production of a non-exploding mechanical admixture of oxygen and hydrogen. Jan. 27.

4548. F. J. Stedman. Apparatus for the production of oxygen gas. Jan. 27.

5686. S. Hersey and Kirkham, Hulett, and Chandler, Ltd. Apparatus for washing, scrubbing, and purifying gas. Feb. 10.

6857. G. Hilgenstock. Coke ovens. Feb. 17.

7463. L. Denayrouze. Incandescent gas lighting. Feb. 17.

16,132. A. Schemidt. Production and purification of acetylene gas, and apparatus therefor; also connected with portable lighting apparatus for burning such gas. Feb. 3.

19,979. A. Rolf. Incandescent gas lights. Feb. 10.

20,501. H. Hill. Manufacture of thread foundations or caps for incandescent mantles. Feb. 17.

25,887. F. J. Collin. Coke furnaces. Feb. 17.

25,167. B. Puchmüller. Process for the manufacture of fluid for impregnating bodies or suitable fabrics, threads, fibres, or the like, for illuminating or lighting purposes. Jan. 27.

26,304. R. Van de Ghinste. Incandescence gas lighting. Feb. 3.

27,086. S. D. Gillet, G. Forest, and J. E. O. Bocande. Burner for lighting by acetylene or other gases rich in carbon. Feb. 3.

27,697. H. H. Lake.—From V. Hanotier and G. Hostelet. Acetylene gas generators. Feb. 3.

29,500. E. Quelle. Apparatus for generating acetylene gas. Feb. 17.

34,134. J. Schumacher. Apparatus for use in generating gas. Feb. 17.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

## APPLICATIONS.

1934. J. E. Whiting. Improvements in the processes for vulcanisation of wood and other organic substances or products. Jan. 25.

2515. H. J. Dawes. Improvements relating to the distillation and breaking up of liquid hydrocarbons and similar substances. Jan. 30.

### IV.—COLOURING MATTERS AND DYES.

## APPLICATIONS.

1320. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of alpha-naphthylamine in an easily diazotisable and stable form. Jan. 18.

1575. H. Baum. Improvements in the manufacture of colouring matter of the rhodamine group. Jan. 20.

1592. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of rhodamine dialkylamides. Jan. 20.

1947. C. D. Abel.—From the Actien Gesellschaft für Anilin Fabrikation. Manufacture of new dyes. Jan. 25.

1962. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Improvements in the manufacture of blue mordant-dyeing colouring matters. Jan. 25.

2655. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Improvements in the manufacture of colouring matters of the rhodamine series. Feb. 1.

2874. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. The manufacture and production of new disazo dyes on cotton. Feb. 3.

3452. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of colouring matters. Feb. 9.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

5857. H. H. Lake.—From The Farbwerk Muhlheim. Manufacture of colouring matters. Feb. 17.

7313. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation. Manufacture of new raw materials and of direct-dyeing colouring matters derived therefrom. Jan. 27.

28,810. W. E. Heyes.—From The Chemical Works, Sandoz. Production of substantive trisazo colouring matters. Jan. 27.

30,015. W. E. Heyes.—From The Chemical Works, Sandoz. Production of violet and blue colouring matters of the triphenylmethane group. Feb. 3.

1897.

304. R. W. James.—From W. J. Matheson and Co., Ltd. Process for the manufacture of aceto-derivatives of the simpler aromatic amines. Feb. 17.

### V.—TEXTILES, COTTON, WOOL, SILK, Etc.

## APPLICATIONS.

2230. W. L. Wise.—From C. A. Kottgen. Improvements in the process for weighting silk or silk waste. Jan. 27.

2549. S. Shorter and S. Stanbridge. Improvements in apparatus for the extraction, cleaning, and preparation of vegetable fibres. Jan. 30.

2736. J. Shearer. Method of improving the colour of raw jute fibre. Feb. 2.

2260. C. O'Brien and J. Shearer. Process for improving the colour of raw jute fibre. Feb. 4.

3218. A. G. Bonbon. Improvements in mercerising textile materials. Feb. 6.

3222. J. Millar. Improvements in textile fabrics or cloths. Feb. 6.

3446. J. Waugh.—From The New Augöburger Cotton Mill Co. Improvements in the washing and boiling treatment of fabrics and materials composed of vegetable fibres. Feb. 11.

3832. R. W. Strehlenert. Improvements in the method of spinning artificial silk, and apparatus therefor. Complete Specification. Filed Feb. 12. Date applied for Aug. 13, 1896, being date of application in Sweden.

## COMPLETE SPECIFICATION ACCEPTED.

1897.

198. F. Walton. Apparatus for manufacturing mosaic floorcloth. Feb. 10.

### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

## APPLICATIONS.

1263. E. Binns and I. Binns. Improvements in appliances to be employed in hank dyeing for spotted or random yarns. Jan. 18.

1629. T. Ingham. An improved dyeing process. Jan. 21.

1744. J. H. Widdicombe. The use of a mixture of gelatin and proteid with a colour powder for transferring designs to cloth and other materials. Jan. 22.

2149. E. Binns and I. Binns. Improvements in hank-dyeing machines. Jan. 27.

2505. J. Sharp. Improvements in dyeing and finishing fabrics. Jan. 30.

2620. W. Watson and E. Bentz. Improvements in and connected with the production of coloured discharge patterns on indigo-dyed cotton fabrics in calico printing. Feb. 1.

3256. H. W. Kearns and J. Barnes. Improvements in the production of fast black upon vegetable fibre. Feb. 8.

### VII.—ACIDS, ALKALIS, AND SALTS.

## APPLICATIONS.

1762. G. D. Howard.—From H. Howard. Improvements in methods of and apparatus for concentrating sulphuric acid or the like. Jan. 22.

1942. The Aluminium Co., Ltd., and A. G. Haddock. Improvements in bleaching compounds. Jan. 25.  
 2308. G. F. Zacher. Improved process for producing oxalic acid. Complete Specification. Jan. 28.  
 2654. C. H. Mehner. An improved method of producing ammonia. Feb. 1.  
 3592. J. E. Campbell. Improvements in apparatus for the concentration or rectification of sulphuric acid or other acids or liquors. Feb. 10.  
 3795. G. G. M. Hardingham.—From T. Huntington and F. Heberlein. See Class X.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

1667. T. Fairley. Manufacture and purification of ammonium nitrate and other salts. Jan. 27.  
 1668. T. Fairley. Manufacture of ammonium nitrate and sodium salts. Jan. 27.  
 2489. W. Garraway. Manufacture of sodium and potassium silicates, and of nitric and sulphuric acids. Jan. 27.  
 3662. A. D. Delsemme. A new or improved process for the purification of carbonic acid gas passing from lime kilns and designed for liquefaction. Feb. 3.  
 5011. P. Duggan. Saturators for use in the manufacture of sulphate of ammonia. Feb. 10.  
 6096. D. A. Peniakoff. Manufacture of aluminate of barium and aluminate of strontium, and the production of alumina sulphate of barium and of strontium and other products from the same. Feb. 3.  
 6835. B. T. L. Thomson. Process and apparatus for the manufacture of carbonic acid gas. Feb. 3.

### VIII.—GLASS, POTTERY, AND ENAMELS.

#### APPLICATIONS.

1432. A. J. Boulton.—From P. A. J. Gasse. Improvements in or relating to the decoration of earthenware, china, glass, tiles, bricks, and the like. Complete Specification. Jan. 19.  
 1614. L. H. Pearce. Improvements in the manufacture of glass articles. Jan. 21.  
 1871. A. E. Doncede. Improved method and means for connecting tubes and pipes of stoneware, earthenware, and glass. Jan. 23.  
 1995. T. Pfister and E. Barthels.—From A. Navarein. Improvements in cloisonné work. Jan. 25.  
 3376. E. W. Brock. New or improved process for transferring printed matter from paper to glass, earthenware, and other enamelled surfaces. Complete Specification. Feb. 9.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

4189. F. Albrecht. Oven for burning or fusing lettering, designs, colours, and the like into or upon articles of glass, earthenware, and other glazed or enamelled goods. Feb. 3.  
 4945. F. Radcliffe. Furnaces suitable for use in the manufacture of glass. Feb. 17.  
 5772. L. A. Garehey. Manufacture of ceramic stone and objects by devitrification of glass. Feb. 3.  
 29,589. F. Joynson, W. Harrison, and G. T. Joynson. Machine for the manufacture of glass bottles, jars, and the like. Feb. 17.

### IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

#### APPLICATIONS.

1795. La Société Metallurgique de Champignoulles et Neuves-Maisons. The manufacture of an improved cement. Filed Jan. 22. Date applied for July 11, 1896, being date of application in France.
